REPRESENTATION OF SOLUTIONS OF PELL EQUATIONS USING LUCAS SEQUENCES

James P. Jones (Calgary, Canada)

Dedicated to the memory of Professor Péter Kiss

Abstract. We consider classes of Pell equations of the form \(x^2 - dy^2 = \pm c\) where \(d = a^2 \pm 4\) or \(d = a^2 \pm 1\) and \(c = \pm 4\) or \(c = \pm 1\). We show that all the solutions are expressible in terms of Lucas sequences and we give the Lucas sequences which solve the equations explicitly.

AMS Classification Number: 11B39, 11B37

1. Introduction

The purpose of this paper is to collect together results concerning the solutions of the Pell equations \(x^2 - (a^2 \pm 4)y^2 = \pm 4\), \(x^2 - (a^2 \pm 4)y^2 = \pm 1\), \(x^2 - (a^2 \pm 1)y^2 = \pm 4\) and \(x^2 - (a^2 \pm 1)y^2 = \pm 1\). We show that the solutions to these Pell equations can all be expressed in terms of Lucas sequences \(U_n(a, \pm 1)\) and \(V_n(a, \pm 1)\) of E. Lucas [20], [21].

The solutions of the Pell equations \(x^2 - (a^2 + 4)y^2 = \pm a,\) \(x^2 - (a^2 - 4)y^2 = 5 - 2a,\) \(x^2 - (a^2 - 4)y^2 = 2 - a\) and \(x^2 - (a^2 - 1)y^2 = 2 - 2a\) can also be represented as Lucas sequences. This is more difficult to prove however and will be shown in a subsequent paper.

The above Pell equations are important to logicians since the sequences of solutions have many elegant divisibility properties which make them useful for diophantine representation of recursively enumerable sets. The above mentioned Pell equations can be found in the papers Y. Matiyasevich [22], [25], M. Davis [1], J. Robinson [26], [27], [28], M. Davis, H. Putnam, J. Robinson [3] and Davis, Matiyasevich and Robinson [2]. Also in the author’s papers [4], [5], [6], [7], and in Jones and Matiyasevich [8], [10]. The above Pell equations also have application to the problem of singlefold diophantine representation of recursively enumerable sets. See Matiyasevich [25] for an explanation, also the paper of Sun Zhiwei [29] and Jones and Matiyasevich [8], [9].

Let \(A\) and \(B\) be integers with \(A \geq 1\) and \(B = \pm 1\). Put \(D = A^2 - 4B\). The Pell equation,

\[
V^2 - DU^2 = \pm 4,
\]
is closely connected with the Lucas identity,

\[(2) \quad V_n^2 - DU_n^2 = 4B^n\]

which is satisfied by the Lucas sequences \(U_n\) and \(V_n\). In the theory developed by E. Lucas [20], [21] and D. H. Lehmer [18], [19], the sequences \(U_n = U_n(A, B)\) and \(V_n = V_n(A, B)\) satisfying equation (2) are definable as second order linear recurrences:

\[(3) \quad V_0 = 2, \quad V_1 = A, \quad V_{n+2} = AV_{n+1} - BV_n,\]

\[(4) \quad U_0 = 0, \quad U_1 = 1, \quad U_{n+2} = AU_{n+1} - BU_n.\]

The Lucas sequences \(V_n\) and \(U_n\) satisfy a large number of other identities as well. We shall need:

\[(5) \quad (i) \quad 2V_{n+1} = AV_n + DU_n, \quad (ii) \quad 2U_{n+1} = AU_n + V_n,\]

\[(6) \quad (i) \quad 2BV_{n-1} = AV_n - DU_n, \quad (ii) \quad 2BU_{n-1} = AU_n - V_n.\]

The above four identities are easy to derive, by induction on \(n\), from the recurrence equations (3) and (4). Using identity (5) (i) it is then easy to show that \(U_n\) and \(V_n\) satisfy the Lucas identity (2). For plainly \(V_n^2 - DU_n^2 = 4B^n\) holds for \(n = 0\). Suppose it holds for \(n\). By (5) (i),

\[
4V_{n+1}^2 - 4DU_{n+1}^2 = (AV_n + DU_n)^2 - D(AU_n + V_n)^2
\]

\[= A^2V_n^2 + D^2U_n^2 - DA^2U_n^2 - DV_n^2 = (A^2 - D)V_n^2 - (A^2 - D)DU_n^2
\]

\[= 4BV_n^2 - 4BDU_n^2 = 4B(V_n^2 - DU_n^2) = 4B4B^n = 16B^{n+1}.
\]

Hence the Lucas identity (2) holds for \(n + 1\) and so by induction (2) holds for all \(n \geq 0\).

One of the main theorems we shall need is that all solutions of \(V^2 - DU^2 = \pm 4\) are given by the Lucas sequences \(V = V_n(A, B)\) and \(U = U_n(A, B)\). And we shall need to know exactly for which pairs \((A, B)\) this holds. We therefore give a careful proof and an exact statement. We will prove the theorem in the following form:

**Theorem 1.1.** Suppose \(D = A^2 - 4B\), \(B = 1\) and \(3B + 5 \leq 2A\). Then for all nonnegative integers \(U\) and \(V\),

\[V^2 - DU^2 = \pm 4 \iff (\exists n \geq 0)[V = V_n(A, B) \text{ and } U = U_n(A, B)]\]
Before giving the proof we mention that the purpose of the hypothesis $3B+5 \leq 2A$ is to exclude some pairs such as $B = 1$ and $A = 3$ for which the theorem does not hold, yet include others such as $B = -1$ and $A = 1$ for which it does hold. If $B = 1$ and $A = 3$, then $D = 5$. $x^2 - 5y^2 = -4$ has infinitely many nonnegative integer solutions $(x, y)$. But they are not all of the form $x = V_n(3, 1)$ and $y = U_n(3, 1)$. For example the solution $(x, y) = (1, 1)$ is not of the form $x = V_n(3, 1)$ and $y = U_n(3, 1)$. Rather $x = V_n(1, -1)$ and $y = U_n(1, -1)$ where $n = 1$. $(x, y)$ lies within the Fibonacci sequence.

Care is therefore necessary in the statement of Theorem 1.1. Not only can Theorem 1.1 fail to hold when $B = 1$ and $A = 3$, the result can fail to hold when we try to generalize it beyond $|B| = 1$. Consider for example the case of $B = 2$. If $A = 4$, then $D = A^2 - 4B = 8$. Now $V = 20$ and $U = 7$ is a solution of $V^2 - 8U^2 = 4B^4$. But $\forall n \neq V_n(4, 2)$ and $\forall n \neq U_n(4, 2)$. Thus Theorem 1.1 does not hold for $B = 2$ and $A = 4$.

2. Descent

Our main tool in the proof we shall give here of Theorem 1.1 will be Fermat’s method of descent. We will apply the method to equation (1). We will need the following lemmas:

**Lemma 2.1.** (Parity Lemma) Suppose $A$ is a positive integer and $|B| = 1$. If $A$ is even, $V_n(A, B)$ is even, and $U_n(A, B)$ is even if $2|n$. If $A$ is odd, $V_n(A, B) \equiv U_n(A, B) \pmod{2}$, and $V_n(A, B)$ and $U_n(A, B)$ are even if $3|n$.

**Proof.** By induction on $n$ using equations (3) and (4).

**Lemma 2.2.** For all $n \geq 0$, $V_{2n}(1, -1) = V_n(3, +1)$ and $U_{2n}(1, -1) = U_n(3, +1)$, ($n = 0, 1, 2, \ldots$).

**Proof.** The proof of this for $V_n$ is the same as that for $U_n$ so we shall give only the proof for $U_n$. For this we use induction on $n$. If $n = 0$ or $n = 1$, then $U_{2n}(1, -1) = U_n(3, 1)$ and $U_{2(n+1)}(1, -1) = U_{n+1}(3, 1)$. Suppose these hold for $n$ and $n+1$. By (4), $U_{2(n+2)}(1, -1) = U_{2n+4}(1, -1) = U_{2n+3}(1, -1) + U_{2n+2}(1, -1)$.

If $V^2 - A^2 = \pm 8$, then $A = 1$ and $V = 3$. 

**Lemma 2.3.** Let $A$ and $V$ be non-negative integers. Then

If $V^2 - A^2 = \pm 8$, then $A = 1$ and $V = 3$. 

If $V^2 - A^2 = -8$, then $A = 3$ and $V = 1$.

**Proof.** $1 \leq |V^2 - A^2| \leq 8 \Rightarrow 1 \leq |V - A|(V + A) \leq 8 \Rightarrow 1 \leq V + A \leq 8$. Hence, if $V^2 - A^2 = +8$, then $A = 1$ and $V = 3$. If $V^2 - A^2 = -8$, then $A = 3$ and $V = 1$.

**Lemma 2.4.**

(Descent Lemma) Suppose $D = A^2 - 4B$, $B = \pm 1$, $B + 2 \leq A$ and $U$ and $V$ are integers such that $0 \leq V$, $2 \leq U$ and $V^2 - DU^2 = \pm 4$. If $V'$ and $U'$ are defined by

\begin{align*}
(7) & \\
(i) & V' = \frac{AV - DU}{2B}, \\
(ii) & U' = \frac{AU - V}{2B},
\end{align*}

then $V'$ and $U'$ are integers and satisfy $V'^2 - DU'^2 = \pm 4B$. Also $V'$ and $U'$ satisfy

\begin{align*}
(8) & \\
(i) & 2V = AV' + DU', \\
(ii) & 2U = AU' + V'.
\end{align*}

Furthermore $1 \leq V'$ and $1 \leq U' < U$.

**Proof.** First we show that $2U \leq V$. Since $D = A^2 - 4B$, $B = \pm 1$ and $B + 2 \leq A$, $5 \leq D$. Since $2 \leq U$ we have $4 \leq U^2$ and so $4U^2 \leq 4U^2 + 4 \leq DU^2 + 4 = V^2$. Therefore $2U \leq V$.

Next we show that $V'$ and $U'$ are integers. $D = A^2 - 4B \Rightarrow D \equiv A^2 \equiv A \pmod{2}$. Also $V^2 - DU^2 = \pm 4 \Rightarrow V^2 \equiv A^2U^2 \pmod{2} \Rightarrow V \equiv AU \pmod{2}$.

Hence $AU - V \equiv 0 \pmod{2}$ and so $U'$ is an integer. Also since $V \equiv AU \pmod{2}$ and $D \equiv A \pmod{2}$, $AV - DU \equiv A^2U - AU \equiv AU - AU = 0 \pmod{2}$ so $V'$ is an integer.

Next we show that $(V')^2 - D(U')^2 = \pm 4B$. From the definitions of $V'$ and $U'$ we have

\[
\frac{V'^2 - DU'^2}{4B^2} = \frac{(AV - DU)^2}{4B^2} - D\left(\frac{AU - V}{2B}\right)^2 = \frac{A^2V^2 - DV^2 - DA^2U^2 + D^2U^2}{4B^2} = \frac{(A^2 - D)(V^2 - DU^2)}{4B^2} = \frac{4B(\pm 4)}{4B^2} = \pm 4B.
\]

Next we show that $2V = AV' + DU'$ and $2U = AU' + V'$. From the definitions of $V'$ and $U'$,

\[
AV' + DU' = A\frac{AV - DU}{2B} + D\frac{AU - V}{2B} = \frac{A^2V - DV}{2B} = \frac{V(A^2 - D)}{2B} = \frac{V4B}{2B} = 2V.
\]

Also

\[
AU' + V' = A\frac{AU - V}{2B} + \frac{AV - DU}{2B} = \frac{A^2U - DU}{2B} = \frac{U(A^2 - D)}{2B} = \frac{U4B}{2B} = 2U.
\]
Next we show that $1 \leq U' < U$. $V^2 - DU^2 = \pm 4 \Rightarrow (A^2 - 4B)U^2 - V^2 = \mp 4 \Rightarrow A^2U^2 - V^2 = 4BU^2 \mp 4 \Rightarrow (AU - V)(AU + V) = 4B(U^2 \mp B)$. Since $2BU' = AU - V \Rightarrow 2BU'(AU + V) = 4B(U^2 \mp B) \Rightarrow U'(AU + V) = 2(U^2 \mp B) = 2U^2 \mp 2B$, we have
\begin{equation}
\frac{2U^2 - 2}{AU + V} \leq U' \leq \frac{2U^2 + 2}{AU + V} \leq \frac{2U^2 + 2}{U + V},
\end{equation}
using $B + 2 \leq A \Rightarrow 1 \leq A$. Since $2 \leq U \Rightarrow 2 < 2U^2 \Rightarrow 0 < 2U^2 - 2$, equation (9) \Rightarrow $0 < U'$. Hence $1 \leq U'$. Now we can show $U' < U$. Using $2U \leq V$, shown earlier, $2U \leq V \Rightarrow 3U \leq U + V$. Also $2 \leq U \Rightarrow 2 < U^2$. Hence by (9),
\begin{equation}
U' \leq \frac{2U^2 + 2}{U + V} \leq \frac{2U^2 + 2}{3U} \leq \frac{2U^2 + U^2}{3U} = U.
\end{equation}
Therefore $U' < U$. Finally we can show that $1 \leq V'$. Since $V' = (AV - DU)/2B$, we have
\begin{equation}
UV' = \frac{AVU - DU^2}{2B} = \frac{AVU - V^2 \pm 4}{2B} = \frac{AVU - V^2}{2B} \pm 2B = UV' \pm 2B.
\end{equation}
Since $1 \leq U'$ and $4 \leq 2U \leq V$, we have $2 \leq 4 \pm 2B \leq 2U \pm 2B \leq 2U' \pm 2B \leq VU' \pm 2B = UV'$ by (11). Hence $2 \leq UV'$ and so $1 \leq V'$. This completes the proof of the Descent Lemma.

**Proof of Theorem 1.1.** Suppose $3B + 5 \leq 2A$. In the direction $\Leftarrow$ Theorem 1.1 has already been proven by our establishing identity (2). For the direction $\Rightarrow$ we use the Descent Lemma and induction on $U$. Suppose $0 \leq U$, $0 \leq V$ and $V^2 - DU^2 = \pm 4$. If $U = 0$, then $V^2 = \pm 4 \Rightarrow V^2 = 4 \Rightarrow V = 2$ and so we can let $n = 0$. Suppose $U = 1$. Then $V^2 - DU^2 = \pm 4 \Rightarrow V^2 - (A^2 - 4B) = \pm 4 \Rightarrow V^2 - A^2 = \pm 4 - 4B$. We consider two cases:

**Case 1.** $B = -1$. Here we have $V^2 - A^2 = 0$ or $V^2 - A^2 = 8$. If $V^2 - A^2 = 0$, then $V = A$ and so we can let $n = 1$ since $V_1(A, B) = A = V$ and $U_1(A, B) = 1 = U$. If $V^2 - A^2 = 8$, then by Lemma 2.3, $A = 1$ and $V = 3$ so we can let $n = 2$ since $V_2(A, B) = A^2 - 2B = 3 = V$ and $U_2(A, B) = A = 1 = U$.

**Case 2.** $B = +1$. Here $V^2 - A^2 = 0$ or $V^2 - A^2 = -8$. If $V^2 - A^2 = -8$, then by Lemma 2.3, $A = 3$ and $V = 1$. Since $B = 1$, $A = 3$ contradicts $3B + 5 \leq 2A$. Hence $V^2 - A^2 = 0$. In this case $V = A$ and so we can let $n = 1$ since $V_1(A, B) = A = V$ and $U_1 = 1 = U$.

Now we can suppose $2 \leq U$ and that the implication $\Rightarrow$ of Theorem 1.1 holds for all pairs $V'$, $U'$ such that $0 \leq U' < U$ and $0 \leq V'$. Since $B = \pm 1$, the hypothesis $3B + 5 \leq 2A$ implies $B + 2 \leq A$ and so we can apply the Descent lemma. Define $V'$ and $U'$ from $V$ and $U$ as indicated in the Descent Lemma: $V' = (AV - DU)/2B$ and $U' = (AV - V)/2B$. The Descent Lemma then asserts
that $V'$ and $U'$ are integers, $1 \leq V' \leq V, 1 \leq U' < U$ and $V'^2 - DU'^2 = \pm 4$. Hence by the induction hypothesis $\exists n \geq 0$ such that $V' = V_n(A, B)$ and $U' = U_n(A, B)$. Consequently using equations (8) in the Descent Lemma and identity (5) (i) we have, $2V = AV' + DU' = AV_n + DU_n = 2V_{n+1}$ and so $V = V_{n+1}$. By (8) and identity (5) (ii) we also have $2U = AU' + V' = AU_n + V_n = 2U_{n+1}$ and so $U = U_{n+1}$. Thus the implication $\Rightarrow$ holds for $U$. By induction the implication $\Rightarrow$ holds for all $U$. Thus Theorem 1. 1 is proved.

**Corollary 2.5.** If $4 \leq A, B = 1, D = A^2 - 4$, then $V^2 - DU^2 = -4$ has no solutions $V, U$.

**Proof.** Of course this follows immediately from Theorem 1. 1 and Lucas Identity (2). But there is a more interesting proof using the Descent Lemma: Suppose $4 \leq A, B = +1$ and $D = A^2 - 4$. Then $B + 2 \leq A$ so we can use the Descent Lemma. Suppose $V^2 - DU^2 = -4$ for some $V, U$. Let $(V, U)$ be the pair with smallest $U$ such that $0 \leq V$ and $0 \leq U$. Then $U \neq 0$. By Lemma 2. 3, $U = 1$ would imply $A = 3$. Hence $2 \leq U$ and so by the Descent Lemma $\exists V'$, $U'$ such that $1 \leq V'$, $1 \leq U' < U$ and $V'^2 - DU'^2 = -4$. But this contradicts the original choice of $U$ and $V$. Thus $V$ and $U$ such that $V^2 - DU^2 = -4$ do not exist.

**Remark.** If $A = 3$, then $V^2 - (A^2 - 4)U^2 = -4$ does have solutions, e.g. $V = 1$ and $U = 1$.

**Corollary 2.6.** If $4 \leq A$, then $x^2 - (a^2 - 4)y^2 = -4$ has no solutions.

**Corollary 2.7.** If $4 \leq A$, then all solutions of $x^2 - (a^2 - 4)y^2 = +4$ are given by $x = V_i(a, +1)$ and $y = U_i(a, +1)$, $(i = 0, 1, 2, \ldots)$.

**Corollary 2.8.** If $1 \leq A$, then all solutions of $x^2 - (a^2 + 4)y^2 = -4$ are given by $x = V_{2i+1}(a, -1)$ and $y = U_{2i+1}(a, -1)$, $(i = 0, 1, 2, \ldots)$.

**Corollary 2.9.** (Matiyasevich equation [22]) If $1 \leq A$, then all solutions of $x^2 - (a^2 + 4)y^2 = +4$ are given by $x = V_{2i}(a, -1)$ and $y = U_{2i}(a, -1)$, $(i = 0, 1, 2, \ldots)$.

**Remark.** In [22] Y. V. Matiyasevich used the above equation $x^2 - (a^2 + 4)y^2 = 4$ with $a = 1$, to solve Hilbert's Tenth Problem. (I.e. he used the sequence of Fibonacci numbers with even subscripts, $U_{2i}(1, -1) = U_i(3, 1)$.)

3. Solutions of Pell equations with $d = a^2 \pm 4$ and $c = \pm 1$.

In this section we give the solutions of Pell equations of the form $x^2 - (a^2 \pm 4)y^2 = \pm 1$.

**Lemma 3.1.** If $4 \leq a$, then $x^2 - (a^2 - 4)y^2 = -1$ has no solutions.

**Proof.** Suppose $4 \leq a$ and $x^2 - (a^2 - 4)y^2 = -1$. Multiplying by 4 we obtain $(2x)^2 - (a^2 - 4)(2y)^2 = -4$, which, since $4 \leq a$, has no solutions by Corollary 2.6.
Remark. If $a = 3$, then $x^2 - (a^2 - 4)y^2 = -1$ has infinitely many solutions, $x = V_{6i+3}(1, -1)/2$ and $y = U_{6i+3}(1, -1)/2$, $(i = 0, 1, 2, \ldots)$. This is shown by the next theorem since $a^2 - 4 = 5 = 1^2 + 4$.

**Theorem 3.2.** If $1 \leq a$ and $a$ is odd, then all solutions of $x^2 - (a^2 + 4)y^2 = -1$ are given by $x = \frac{V_n(a, -1)}{2}$ and $y = \frac{U_n(a, -1)}{2}$, $(i = 0, 1, 2, \ldots)$.

**Proof.** Using Corollary 2.8, since $1 \leq a$, we have $x^2 - (a^2 + 4)y^2 = -1 \Leftrightarrow (2x)^2 - (a^2 + 4)(2y)^2 = -4 \Leftrightarrow 2x = V_n(a, -1)$ and $2y = U_n(a, -1)$ for some odd $n$. As $a$ is odd, by the Parity Lemma $2|V_n(a, -1)$ and $2|U_n(a, -1) \Leftrightarrow 3|n$, $3|n$ and $n$ is odd $\Leftrightarrow 3i = n = 6i + 3$, $(i = 0, 1, 2, \ldots)$.

**Lemma 3.3.** For any even integer $a$, $x^2 - (a^2 + 4)y^2 = -1$ has no solutions.

**Proof.** Suppose $a$ is even. Then $4|a^2 \Rightarrow 4|a^2 - 4$. But $x^2 \neq -1 \pmod{4}$.

**Theorem 3.4.** If $4 \leq a$ and $a$ is even, then all solutions of $x^2 - (a^2 - 4)y^2 = +1$ are given by $x = \frac{V_n(a, +1)}{2}$ and $y = \frac{U_n(a, +1)}{2}$, $(i = 0, 1, 2, \ldots)$.

**Proof.** Using Corollary 2.7, since $4 \leq a$, we have $x^2 - (a^2 - 4)y^2 = +1 \Leftrightarrow (2x)^2 - (a^2 - 4)(2y)^2 = +4 \Leftrightarrow \exists n \geq 0$, $2x = V_n(a, +1)$ and $2y = U_n(a, +1)$. Since $2|a$, the Parity Lemma implies $2|V_n(a, +1)$ and $2|U_n(a, +1) \Leftrightarrow 2|n$, i.e. $n = 2i$, $(i = 0, 1, 2, \ldots)$.

**Theorem 3.5.** If $3 \leq a$ and $a$ is odd, then all solutions of $x^2 - (a^2 - 4)y^2 = +1$ are given by $x = \frac{V_n(a, +1)}{2}$ and $y = \frac{U_n(a, +1)}{2}$, $(i = 0, 1, 2, \ldots)$.

**Proof.** Suppose $3 \leq a$ and $a$ is odd. $x^2 - (a^2 - 4)y^2 = +1 \Leftrightarrow (2x)^2 - (a^2 - 4)(2y)^2 = +4$. If $3 < a$, then by Corollary 2.7, $2x = V_n(a, +1)$ and $2y = U_n(a, +1)$, where, by the Parity Lemma, $n = 3i$, $(i = 0, 1, 2, \ldots)$. If $3 = a$, then, since $a^2 - 4 = 5 = 1^2 + 4$, Corollary 2.9, $2x = V_2(1, -1)$ and $2y = U_2(1, -1)$, where $j = 3i$, $(i = 0, 1, 2, \ldots)$ by the Parity Lemma, so that $x = V_{6i}(1, -1)/2$ and $y = U_{6i}(1, -1)/2$, $(i = 0, 1, 2, \ldots)$. However by Lemma 2.2, $V_{6i}(1, -1) = V_{3i}(3, +1)$ and $U_{6i}(1, -1) = U_{3i}(3, +1)$, $(i = 0, 1, 2, \ldots)$ as required.

**Theorem 3.6.** If $2 \leq a$ and $a$ is even, then all solutions of $x^2 - (a^2 + 4)y^2 = +1$ are given by $x = \frac{V_n(a, -1)}{2}$ and $y = \frac{U_n(a, -1)}{2}$, $(i = 0, 1, 2, \ldots)$.

**Proof.** By Corollary 2.9, since $2 \leq a$, we have $x^2 - (a^2 + 4)y^2 = +1 \Leftrightarrow (2x)^2 - (a^2 + 4)(2y)^2 = +4 \Leftrightarrow 2x = V_n(a, -1)$ and $2y = U_n(a, -1)$ for some even $n$. Since $2|a$ and $n$ is even, the Parity Lemma implies $2|V_n(a, -1)$ and $2|U_n(a, -1)$.

**Theorem 3.7.** If $1 \leq a$ and $a$ is odd, then all solutions of $x^2 - (a^2 + 4)y^2 = +1$ are given by $x = \frac{V_n(a, -1)}{2}$ and $y = \frac{U_n(a, -1)}{2}$, $(i = 0, 1, 2, \ldots)$.

**Proof.** By Corollary 2.9, since $1 \leq a$, we have $x^2 - (a^2 + 4)y^2 = +1 \Leftrightarrow (2x)^2 - (a^2 + 4)(2y)^2 = +4 \Leftrightarrow 2x = V_n(a, -1)$ and $2y = U_n(a, -1)$ for some even $n$. Since...
a is odd, the Parity Lemma implies $2|V_n(a, -1)$ and $2|U_n(a, -1) \iff 3|n$. $2|n$ and $3|n \iff 6|n$. Hence $n = 6i \ (i = 0, 1, 2, \ldots)$.

4. Solutions of Pell equations with $d = a^2 \pm 1$ and $c = \pm 1$.

In this section we consider solutions of Pell equations of the form $x^2 - (a^2 \pm 1)y^2 = \pm 1$.

Lemma 4.1. If $2 \leq a$, then $x^2 - (a^2 - 1)y^2 = -1$ has no solutions.

Proof. Suppose $2 \leq a$ and $x^2 - (a^2 - 1)y^2 = -1$. Multiplying by 4 we obtain $(2x)^2 - ((2a)^2 - 4)y^2 = -4$. Since $4 \leq 2a$, this equation has no solutions by Corollary 2. 6.

[Another proof is also possible. Let $d = a^2 - 1$. The continued fraction expansion of $\sqrt{d}$ is $[a - 1; \overline{1, 2a - 2}]$ with period length 2 (even). Hence $x^2 - dy^2 = -1$ is unsolvable.]

Theorem 4.2. (Julia Robinson’s equation [26], [27]) If $2 \leq a$, then all solutions of $x^2 - (a^2 - 1)y^2 = +1$ are given by $x = \frac{V_n(2a, +1)}{2}$ and $y = U_n(2a, +1), \ (i = 0, 1, 2, \ldots)$.

Proof. Suppose $2 \leq a$. Using Corollary 2.7, since $4 \leq 2a$ we have $x^2 - (a^2 - 1)y^2 = +1 \iff (2x)^2 - ((2a)^2 - 4)y^2 = +4 \iff \exists \ n \geq 0, 2x = V_n(2a, +1)$ and $y = U_n(2a, +1)$. Since $2a$ is even, the Parity Lemma implies $V_n(2a, +1)$ is even. Hence $2|V_n(2a, +1)$.

Theorem 4.3. If $1 \leq a$, then all solutions of $x^2 - (a^2 + 1)y^2 = +1$ are given by $x = \frac{V_n(2a, -1)}{2}$ and $y = U_n(2a, -1), \ (i = 0, 1, 2, \ldots)$.

Proof. Using Corollary 2.9, since $1 \leq 2a$, we have $x^2 - (a^2 + 1)y^2 = +1 \iff (2x)^2 - ((2a)^2 + 4)y^2 = +4 \iff 2x = V_n(2a, -1)$ and $y = U_n(2a, -1)$ for some even $n, n = 2i, \ (i = 0, 1, 2, \ldots)$. Since $2a$ is even, the Parity Lemma implies $2|V_n(2a, -1)$.

Theorem 4.4. If $1 \leq a$, then all solutions of $x^2 - (a^2 + 1)y^2 = -1$ are given by $x = \frac{V_n(2a, -1)}{2}$ and $y = U_n(2a, -1), \ (i = 0, 1, 2, \ldots)$.

Proof. Using Corollary 2.8, since $1 \leq 2a$, we have $x^2 - (a^2 + 1)y^2 = -1 \iff (2x)^2 - ((2a)^2 + 4)y^2 = -4 \iff 2x = V_n(2a, -1)$ and $y = U_n(2a, -1)$ for some odd $n, n = 2i + 1, \ (i = 0, 1, 2, \ldots)$. The Parity Lemma implies $2|V_n(2a, -1)$, since $2a$ is even.
5. Solutions of Pell equations with \( d = a^2 \pm 1 \) and \( c = \pm 4 \).

In this section we consider solutions of Pell equations of the form \( x^2 - (a^2 \pm 1)y^2 = \pm 4 \).

**Lemma 5.1.** If \( 2 \leq a, a \neq 3 \) and \( x^2 - (a^2 - 1)y^2 = \pm 4 \), then \( y \) is even.

**Proof.** Let \( d = a^2 - 1 \). Suppose \( 2 \leq a, a \neq 3 \) and \( x^2 - dy^2 = \pm 4 \). If \( a \) is even, then \( 4|a^2 \) and so \( d \equiv -1 \) (mod 4). Hence \( x^2 - dy^2 = \pm 4 \Rightarrow x^2 + y^2 \equiv 0 \) (mod 4) \( \Rightarrow y \equiv x \equiv 0 \) (mod 2). Therefore we can suppose \( a \) is odd and \( 5 \leq a \). Then \( 4|d \) and so \( x \) is even. Suppose \( y \) is odd, and without loss of generality that \( y \) is the least such odd \( y > 0 \). Since \( 3 < a \), \( (a - 1)^2 < a^2 - 5 < a^2 + 3 < (a + 1)^2 \). Hence \( d \equiv 4 \) is not a square and so \( y \neq 1 \). Therefore \( 2 < y \). Let \( x' = ax - dy \) and \( y' = ay - x \). Then

\[
x^2 - dy^2 = (ax - dy)^2 - d(ay - x)^2 = (a^2 - d)x^2 - d(a^2 - d)y^2 = x^2 - dy^2 = \pm 4.
\]

Hence \((x', y')\) is also a solution. Since \( x \) is even and \( a \) and \( y \) are both odd, \( y' \) is odd. Now \( 5 \leq a \) and \( 2 < y \Rightarrow 2y'(1 - a) < \pm 4 < y^2 \iff 2y^2 - 2ay^2 < \pm 4 < y^2 \iff y^2 - 2ay^2 < -y^2 \pm 4 < 0 \iff a^2y^2 - 2ay^2 + y^2 < a^2y^2 - y^2 \pm 4 < a^2y^2 \iff (a^2 - 2a + 1)y^2 < (a^2 - 1)y^2 \pm 4 < a^2y^2 \iff (a - 1)^2y^2 < x^2 < a^2y^2 \iff (a - 1)y < x < ay \iff 0 < ay - x < y \iff 0 < y' < y \). But since \( x^2 - dy^2 = \pm 4 \) and \( y' \) is odd, this contradicts the choice of \( y \). Hence no such odd \( y \) exists.

**Lemma 5.2.** If \( 1 \leq a, a \neq 2 \) and \( x^2 - (a^2 + 1)y^2 = \pm 4 \), then \( y \) is even.

**Proof.** Let \( d = a^2 + 1 \). Suppose \( 1 \leq a, a \neq 2 \) and \( x^2 - dy^2 = \pm 4 \). If \( a \) is odd, then \( a^2 \equiv 1 \) (mod 4) and so \( d \equiv 2 \) (mod 4). Hence \( x^2 - dy^2 = \pm 4 \Rightarrow x^2 + 2y^2 \equiv 0 \) (mod 4) \( \Rightarrow y \equiv x \equiv 0 \) (mod 2). Consequently we can suppose \( a \) is even and since \( a \neq 2 \), that \( 4 \leq a \). Suppose \( y \) is odd and \( y \) is the least such odd \( y > 0 \). Since \( d \) is odd and \( y \) is odd, \( x \) must be odd. Since \( 2 < a, (a - 1)^2 < a^2 - 3 < a^2 + 5 < (a + 1)^2 \), so that \( d \pm 4 \) is not a square and hence \( y \neq 1 \). Thus \( 2 < y \). Put \( x' = dy - ax \) and \( y' = x - ay \). As in the proof of Lemma 5.1, \( x^2 - dy^2 = \pm 4 \). Since \( y' = x - ay \), \( x \) is odd and \( a \) is even, \( y' \) is odd. Now \( 2 < a \) and \( 2 < y \Rightarrow -y^2 < \pm 4 < 2ay^2 \iff 0 < y^2 < 2ay^2 + y^2 \iff a^2y^2 < a^2y^2 + y^2 < a^2y^2 + 2ay^2 + y^2 \iff a^2y^2 < (a^2 + 1)y^2 < (a + 1)^2y^2 \iff a^2y^2 < x^2 < (a + 1)^2y^2 \iff ay < x < (a + 1)y \).
0 < x - ay < y \iff 0 < y' < y. But since \( x^2 - dy^2 = \pm 4 \) and \( y' \) is odd, this contradicts the choice of \( y \). Hence no such odd \( y \) exists.

**Theorem 5.3.** If \( 2 \leq a \) and \( a \neq 3 \), then all solutions of \( x^2 - (a^2 - 1)y^2 = 4 \) are given by \( x = V_i(2a, +1) \) and \( y = 2U_i(2a, +1), (i = 0, 1, 2, \ldots) \).

**Proof.** Suppose \( 2 \leq a, a \neq 3 \) and \( x^2 - (a^2 - 1)y^2 = 4 \). By Lemma 5.1, 2|y. Let \( y = 2u \). \( x^2 - (a^2 - 1)y^2 = 4 \iff x^2 - (a^2 - 1)4u^2 = 4 \iff x^2 - ((2a)^2 - 4)u^2 = 4 \iff x = V_i(2a, +1) \) and \( u = U_i(2a, +1) \) for some \( i \), by Corollary 2.7, since \( 4 \leq 2a \).

**Theorem 5.4.** If \( 1 \leq a \) and \( a \neq 2 \), then all solutions of \( x^2 - (a^2 + 1)y^2 = 4 \) are given by \( x = V_i(2a, -1) \) and \( y = 2U_i(2a, -1), (i = 0, 1, 2, \ldots) \).

**Proof.** Suppose \( 1 \leq a, a \neq 2 \) and \( x^2 - (a^2 + 1)y^2 = 4 \). By Lemma 5.2, 2|y. Let \( y = 2u \). \( x^2 - (a^2 + 1)y^2 = 4 \iff x^2 - (a^2 + 1)4u^2 = 4 \iff x^2 - ((2a)^2 + 4)u^2 = 4 \iff x = V_i(2a, -1) \) and \( u = U_i(2a, -1) \) for some \( i \), (i = 0, 1, \ldots), by Corollary 2.9, since \( 1 \leq 2a \).

**Theorem 5.5.** If \( 1 \leq a \) and \( a \neq 2 \), then all solutions of \( x^2 - (a^2 + 1)y^2 = -4 \) are given by \( x = V_{2i+1}(2a, -1) \) and \( y = 2U_{2i+1}(2a, -1), (i = 0, 1, 2, \ldots) \).

**Proof.** Suppose \( 1 \leq a, a \neq 2 \) and \( x^2 - (a^2 + 1)y^2 = -4 \). By Lemma 5.2, 2|y. Let \( y = 2u \). \( x^2 - (a^2 + 1)y^2 = -4 \iff x^2 - (a^2 + 1)4u^2 = -4 \iff x^2 - ((2a)^2 + 4)u^2 = -4 \iff x = V_{2i+1}(2a, -1) \) and \( u = U_{2i+1}(2a, -1) \) for some \( i \), (i = 0, 1, \ldots), by Corollary 2.8, since \( 1 \leq 2a \).

**Theorem 5.6.** If \( 2 \leq a \) and \( a \neq 3 \), then \( x^2 - (a^2 - 1)y^2 = -4 \) has no solutions.

**Proof.** Suppose \( 2 \leq a, a \neq 3 \) and \( x^2 - (a^2 - 1)y^2 = -4 \). By Lemma 5.1, 2|y. Let \( y = 2u \). Then \( x^2 - (a^2 - 1)y^2 = -4 \Rightarrow x^2 - (a^2 - 1)4u^2 = -4 \Rightarrow x^2 - ((2a)^2 - 4)u^2 = -4 \). But this equation has no solutions by Corollary 2.6, since \( 4 \leq 2a \).
