ALMOST PERIODIC MILD SOLUTIONS OF A CLASS
OF PARTIAL FUNCTIONAL DIFFERENTIAL EQUATIONS

BERND AULBACH AND NGUYEN VAN MINH

Abstract. We study the existence of almost periodic mild solutions of a
class of partial functional differential equations via semilinear almost peri-
odic abstract functional differential equations of the form

\[ x' = f(t, x, x_t) \]  \hspace{1cm} (\ast)

To this end, we first associate with every almost periodic semilinear equation

\[ x' = F(t, x) \]  \hspace{1cm} (\ast\ast)

a nonlinear semigroup in the space of almost periodic functions. We then
give sufficient conditions (in terms of the accretiveness of the generator of
this semigroup) for the existence of almost periodic mild solutions of (\ast\ast)
as fixed points of the semigroup. Those results are then carried over to
equation (\ast). The main results are stated under accretiveness conditions of
the function \( f \) in terms of \( x \) and Lipschitz conditions with respect to \( x_t \).

1. Introduction

In this paper we are mainly concerned with the existence of almost peri-
odic semilinear evolution equations of the form

\[ \frac{dx}{dt} = Ax + f(t, x, x_t) \]  \hspace{1cm} (1)

where \( A \) is the infinitesimal generator of a \( C_0 \)-semigroup \( T(t), t \geq 0 \) and
\( f \) is an everywhere defined continuous operator from \( \mathbb{R} \times X \times C \) to \( X \).
Throughout this paper we will denote by \( C = C_u((-\infty, 0], X) \) the space of
all uniformly continuous and bounded functions from \( (-\infty, 0] \) to \( X \), by \( X \) a

given Banach space and by \( x_t \) the map \( x(t + \theta) = x_t(\theta), \) \( \theta \in (-\infty, 0] \), where \( x(\cdot) \) is defined on \( (-\infty, a] \) for some \( a > 0 \).

As is well known (see e.g. [2], [5], [10], [12], [18-19], [24-27], [37] and the references therein) many problems on partial differential equations can be stated in the setting of abstract functional differential equations of the form (1). In passing we mention that the case \( A = 0 \) of equation (1) has been treated in [13-17], [28], [31]. In these papers the proofs of the main results are based on an existence theorem for bounded solutions due to Medvedev [20].

Recently, increasing interest in semilinear evolution equations can be observed (see e.g. [12], [18-19], [25-27], [32] and the references therein). This interest arises from a need to extend well-known results on ordinary differential equations to a class of partial differential equations. In this context we consider the existence of almost periodic mild solutions of equation (1). At this point we want to emphasize that our approach to the problem is somewhat different from that used in the papers [13-17], [28], [31]. In fact, we first associate with an equation without delay (equation (2) below) a semigroup of nonlinear operators which then plays a role similar to that of monodromy operator for equations with periodic coefficients. Then we use the results thus obtained in order to study equation (1). Our method, in the case \( A = 0 \), requires a condition on \( f \) which is somewhat stronger than that used in the previous papers in order to guarantee the existence of the associated semigroups. However, our method in turn allows to impose accretiveness conditions on the function \( f \) in a more general context which seems to be more suitable for equations whose right-hand side \( f \) depends explicitly on \( t \).

### 2. Almost Periodic Solutions of Differential Equations without Delay

In this section we deal with almost periodic mild solutions to the semilinear evolution equation

\[
\frac{dx}{dt} = Ax + f(t, x), \quad x \in X
\]  

(2)

where \( X \) is a Banach space, \( A \) is the infinitesimal generator of a \( C_0 \)-semigroup \( S(t), t \geq 0 \) of linear operators of type \( \omega \), i.e.

\[
\|S(t)x - S(t)y\| \leq e^{\omega t}\|x - y\|, \forall t \geq 0, \; x, y \in X,
\]

and \( B \) is an everywhere defined continuous operator from \( \mathbb{R} \times X \) to \( X \). Hereafter, by a mild solution \( x(t), t \in [s, \tau] \) of equation (2) we mean a continuous solution of the integral equation

\[
x(t) = S(t-s)x + \int_s^t S(t-\xi)B(\xi, x(\xi))d\xi, \; \forall s \leq t \leq \tau.
\]  

(3)

A strong solution (for the definition see [34], e.g.) of equation (2) is necessarily a mild solution of this equation. The inverse assertion, however, is not true for a general Banach space \( X \) (see [34] for a counter-example). On the
other hand, under additional assumptions on $X$ the mild solutions may be strong solutions. For more information on semilinear equations of the form (2) we refer to [12], [19], [24-25], [34].

Before proceeding we recall some notions and results which will be frequently used later on. We define the bracket $[\cdot, \cdot]$ in a Banach space $Y$ as follows (see [5], [19])

$$[x,y] = \lim_{h \to +0} \frac{\|x + hy\| - \|y\|}{h} = \inf_{h > 0} \frac{\|x + hy\| - \|y\|}{h}$$

**Definition 1.** Suppose that $F$ is a given operator in a Banach space $Y$. Then $(F + \gamma I)$ is said to be accretive if and only if for every $\lambda > 0$ one of the following equivalent conditions is satisfied

i) $(1 - \lambda \gamma)\|x - y\| \leq \|x - y + \lambda(Fx - Fy)\|$, $\forall x, y \in D(F)$,

ii) $[x - y, Fx - Fy] \geq -\gamma\|x - y\|$, $\forall x, y \in D(F)$.

In particular, if $\gamma = 0$, then $F$ is said to be accretive.

**Remark.** From this definition we may conclude that $(F + \gamma I)$ is accretive if and only if

$$\|x - y\| \leq \|x - y + \lambda(Fx - Fy)\| + \lambda \gamma \|x - y\|$$

for all $x, y \in D(F), \lambda > 0, 1 \geq \lambda \gamma$.

**Definition 2.** (Condition H1). Equation (2) is said to satisfy condition H1 if

i) $A$ is the infinitesimal generator of a linear semigroup $S(t)$, $t \geq 0$ of type $\omega$ in $X$,

ii) $B$ is an everywhere defined continuous operator from $\mathbb{R} \times X$ to $X$,

iii) For every fixed $t \in \mathbb{R}$, the operator $(-B(t, \cdot) + \gamma I)$ is accretive in $X$.

The following well-known results are quoted for the reader’s convenience (see [12], [19], [34]).

**Theorem 1.** Let equation (2) satisfy condition H1. Then for every fixed $s \in \mathbb{R}$ and $x \in X$ there exists a unique mild solution $x(\cdot)$ of equation (2) defined on $[s, +\infty)$. Moreover, if $B$ is independent of $t$, then the mild solutions of equation (2) give rise to a semigroup of nonlinear operators $T(t), t \geq 0$ having the following properties:

i) $T(t)x = S(t)x + \int_0^t S(t - \xi)BTx\,d\xi, \forall t \geq 0, x \in X$, (5)

ii) $\|T(t)x - T(t)y\| \leq e^{(\omega + \gamma)t}\|x - y\|, \forall t \geq 0, x, y \in X$. (6)

Throughout this paper we shall denote by $AP(X)$ the space of almost periodic $X$-valued functions in Bohr’s sense with supremum norm, i.e. the space of continuous functions $f$ from $\mathbb{R}$ to $X$ such that the set $\{f(\cdot + s) : \mathbb{R} \to X | s \in \mathbb{R}\}$ is precompact in the space of functions $\{f : \mathbb{R} \to X | f$ bounded and continuous$\}$ equipped with the supremum norm.

The following condition will be used frequently:
Definition 3. (Condition H2). Equation (2) is said to satisfy condition H2 if for every \( u \in AP(X) \) the function \( B(\cdot, u(\cdot)) \) belongs to \( AP(X) \) and if the operator \( B_\ast \) taking \( u \) into \( B(\cdot, u(\cdot)) \) is continuous.

The main point of our study is to associate with equation (2) an evolution semigroup which plays a role similar to that of the monodromy operator for equations with periodic coefficients. Hereafter we will denote by \( U(t,s) \), \( t \geq s \), the evolution operator corresponding to equation (2) which satisfies the assumptions of Theorem 1, i.e. \( U(t,s)x \) is the unique solution of equation (3).

Proposition 1. Let the conditions H1 and H2 be satisfied. Then with equation (2) one can associate an evolution semigroup \( T^h, h \geq 0 \) acting on \( AP(X) \), defined as

\[
[T^h v](t) = U(t, t-h)v(t-h), \forall h \geq 0, \quad t \in \mathbb{R}, v \in AP(X).
\]

Moreover, this semigroup has the following properties:

i) \( T^h, h \geq 0 \) is strongly continuous, and

\[
T^h u = S^h u + \int_0^h S^{h-\xi} B_\ast(T^\xi u)d\xi, \quad \forall h \geq 0, u \in AP(X),
\]

where \( (S^h u)(t) = S(h)u(t-h), \forall h \geq 0, t \in \mathbb{R}, u \in AP(X) \).

ii) \( \|T^h u - T^h v\| \leq e^{(\omega+\gamma)h}\|u - v\|, \forall h \geq 0, u, v \in AP(X) \).

Proof. We first look at the solutions to the equation

\[
w(t) = S^{t-a} + \int_a^t S^{t-\xi} B_\ast(w(\xi))d\xi \quad \forall \xi \in AP(X), t \geq a \in \mathbb{R}.
\]

(7)

It may be noted that \( S^h, h \geq 0 \) is a strongly continuous semigroup of linear operators in \( AP(X) \) of type \( \omega \). Furthermore, for \( \lambda > 0, \lambda\gamma < 1 \) and \( u, v \in AP(X) \), from the accretiveness of the operators \( -B(t, \cdot) + \gamma I \) we get

\[
(1 - \lambda\gamma)\|x - y\| = (1 - \lambda\gamma)\sup_t \|u(t) - v(t)\|
\]

\[
= \sup_t (1 - \lambda\gamma)\|u(t) - v(t)\|
\]

\[
\leq \sup_t \|u(t) - v(t) - \lambda[B(t, u(t)) - B(t, v(t))]|\|
\]

\[
= \|u - v - \lambda(B_\ast u - B_\ast v)\|.
\]

(8)

This shows that \( (-B_\ast + \gamma I) \) is accretive. In virtue of Theorem 1 there exists a semigroup \( T^h, h \geq 0 \) such that

\[
T^h u = S^h u + \int_0^h S^{h-\xi} B_\ast(T^\xi u)d\xi,
\]

\[
\|T^h u - T^h v\| \leq e^{(\omega+\gamma)h}\|u - v\|, \forall h \geq 0, u, v \in AP(X).
\]

From this we get

\[
{T^h u}(t) = [S^h u](t) + \int_0^h [S^{h-\xi} B_\ast(T^\xi u)](t)d\xi, \forall t \in \mathbb{R}.
\]
Thus
\[ [T^h u](t) = S(h)u(t - h) + \int_0^h S(h - \xi)[B(T^\xi u)(t - h + \xi)]d\xi \]
\[ = S(h)u(t - h) + \int_0^h S(h - \xi)B(t + \xi - h, [T^u](t + \xi - h))d\xi \]
\[ = S(h)u(t - h) + \int_{t-h}^t S(t - \eta)B(\eta, [T^{\eta-(t-h)}]u)[\eta]d\eta. \]

If we denote \([T^{t-s}u](t)\) by \(x(t)\), we get
\[ x(t) = S(t - s)z + \int_s^t S(t - \xi)B(\xi, x(\xi))d\xi, \forall t \geq s, \quad (9) \]
where \(z = u(s)\). Consequently, from the uniqueness of mild solutions of equation (2) we get \([T^{t-s}u](t) = x(t) = U(t, s)u(s)\) and \([T^h u](t) = U(t, t - h)u(t - h)\) for all \(t \geq s, u \in AP(Q)\). This completes the proof of the proposition.

The main idea underlying our approach is the following assertion.

**Corollary 1.** Let all assumptions of Proposition 1 be satisfied. Then a mild solution \(x(t)\) of equation (1), defined on the whole real line \(R\), is almost periodic if and only if it is a common fixed point of the evolution semigroup \(T^h\), \(h \geq 0\) defined in Proposition 1 above.

**Proof.** Suppose that \(x(t)\), defined on the real line \(R\), is an almost periodic mild solution of equation (2). Then from the uniqueness of mild solutions we get
\[ x(t) = U(t, t - h)x(t - h) = [T^h x](t), \forall t \in R. \]
This shows that \(x\) is a fixed point of \(T^h\) for every \(h > 0\). Conversely, suppose that \(y(\cdot)\) is any common fixed point of \(T^h\), \(h \geq 0\). Then
\[ y(t) = [T^{t-s}y](t) = U(t, s)y(s), \forall t \geq s. \]
This shows that \(y(\cdot)\) is a mild solution of equation (2).

We now apply Corollary 1 in order to get sufficient conditions for the existence of almost periodic mild solutions of equation (2).

**Corollary 2.** Let all conditions of Proposition 1 be satisfied. Furthermore, let \(\omega + \mu\) be negative and \(-B_* - \mu I\) be accretive. Then there exists a unique almost periodic mild solution of equation (2).

**Proof.** It is obvious that there exists a unique common fixed point of the semigroup \(T^h\), \(h \geq 0\). The assertion now follows from Corollary 1.

**Remark.** A particular case in which we can check the accretiveness of \(-B_* - \mu I\) is \(\omega + \gamma < 0\). In fact, this follows easily from the above estimates for \(\|u - v\|\) (see the estimate (8)).
Another "hyperbolic" case in which there exists a unique common fixed point for the semigroup $T^h, h \geq 0$ can be described as follows.

**Definition 4.** A semigroup $S(t), t \geq 0$ of linear operators in a Banach space $X$ is said to be hyperbolic if there exist positive constants $K, \alpha$ and a bounded projection $P$ of $X$ with the following properties:

i) $PS(t) = S(t)P, \forall t \geq 0,$

ii) $(I - P)S(t)(I - P)$ is a homeomorphism of Ker$P, \forall t \geq 0,$

iii) $||[(I - P)S(t)(I - P)]^{-1}|| \leq Ke^{-\alpha t}$ and $||PS(t)P|| \leq Ke^{\alpha t}, \forall t \geq 0.$

**Corollary 3.** Let all conditions of Proposition 1 be satisfied. Moreover, let $A$ be the infinitesimal generator of a hyperbolic semigroup and let $B(t, x)$ satisfy the estimate

$$||B(t, x) - B(t, y)|| \leq \delta||x - y||, \forall t \in \mathbb{R}, x, y \in X.$$ 

Then, for $\delta$ sufficiently small, equation (2) has a unique almost periodic mild solution.

**Proof.** It may be seen that

$$||U(t, s)x - U(t, s)y|| \leq e^{\omega(t-s)}||x - y|| + \int_s^t e^{\omega(t-\xi)}\delta||U(\xi, s)x - U(\xi, s)y||d\xi.$$ 

Using Gronwall’s inequality we get

$$||U(t, s)x - U(t, s)y|| \leq e^{(\omega+\delta)(t-s)}||x - y||, \forall t \geq s, x, y \in X.$$ 

Consequently,

$$||(U(t, s)x - S(t-s)x) - (U(t, s)y - S(t-s)y)|| \leq$$

$$\leq \delta \int_s^t e^{\omega(t-\xi)}||U(\xi, s)x - U(\xi, s)y||d\xi \leq$$

$$\leq \delta \int_s^t e^{\omega(t-\xi)}e^{(\omega+\delta)(\xi-s)}d\xi ||x - y|| =$$

$$= \delta(t-s)e^{\omega}(t-s)||x - y||, \forall t \geq s, x, y \in X.$$ 

Applying this in order to estimate the Lipschitz constant of $T^1 - S^1$ we get

$$||(T^1 - S^1)u - (T^1 - S^1)v|| =$$

$$= \sup_t ||[U(t, t-1)u(t-1) - S(1)u(t-1)] -$$

$$- [U(t, t-1)v(t-1) - S(1)v(t-1)]|| \leq$$

$$\leq \sup_t \delta e^{\omega}||u(t) - v(t)|| \leq \delta||u - v||, \forall u, v \in AP(X).$$ 

Since $S^1$ is hyperbolic, 1 does not belong to the spectrum $\sigma(S^1).$ Consequently, applying the Inverse Function Theorem for Lipschitz continuous mappings (see e.g. [19, Proposition 2.3, p. 67]) we observe that if $\delta e^{\omega} < ||(S^1 - I)^{-1}||,$ the mapping $T^1 - I$ is invertible and then it has a unique fixed point. Finally, this is a unique common fixed point for the semigroup $T^h, h \geq 0.$ Now the assertion of the corollary follows from Corollary 1. ■
3. Almost Periodic Solutions of Differential Equations with Delays

In this section we apply the results of the previous section in order to study the existence of almost periodic mild solutions of the equation

\[ \frac{dx}{dt} = Ax + f(t, x, x_t) \]

where \( A \) is defined as in Section 2, and \( f \) is an everywhere defined continuous mapping from \( \mathbb{R} \times X \times C \) to \( X \). Hereafter we call a continuous function \( x(t) \) defined on the real line \( \mathbb{R} \) a mild solution of equation (1) if

\[ x(t) = S(t - s)x(s) + \int_s^t S(t - \xi)f(\xi, x(\xi), x_\xi)d\xi, \quad \forall t \geq s. \]

We refer the reader to [32] for more information on the existence and uniqueness of mild solutions of equations of the form (1). We should emphasize that our study is concerned only with the existence of almost periodic mild solutions of equation (1), and not with mild solutions in general. Consequently, the conditions guaranteeing the existence and uniqueness of mild solutions of equation (1) as general as in [32] are not supposed to be a priori conditions.

**Definition 5.** (Condition H3). Equation (1) is said to satisfy Condition H3 if the following is true:

i) For every \( g \in AP(X) \) the mapping \( F(t, x) = f(t, x, g_t) \) satisfies conditions H1 and H2 with the same constant \( \gamma \).

ii) There exists a constant \( \mu \) with \( \omega - \mu < 0 \) such that \( -(\mu I + F_s) \) is accretive for every \( g \in AP(X) \).

iii) \( \| x - y, f(t, x, \phi) - f(t, y, \phi') \| \leq \gamma\| x - y \| + \delta\| \phi - \phi' \|, \quad \forall t \in \mathbb{R}, x, y \in X, \phi, \phi' \in C. \)

**Theorem 2.** Let condition H3 hold. Then for \( \delta \) sufficiently small (see the estimate (13) below), equation (1) has an almost periodic mild solution.

**Proof.** First we fix a function \( g \in AP(X) \). In view of Proposition 1 we observe that the equation

\[ \frac{dx}{dt} = Ax + F(t, x) \]

has a unique almost periodic mild solution, where \( F(t, x) = f(t, x, g_t) \). We denote this solution by \( Tg \). Thus, we have defined an operator \( T \) acting on \( AP(X) \). We now prove that \( T \) is a strict contraction mapping. In fact, let us denote by \( U(t, s) \) and \( V(t, s) \) the Cauchy operators

\[ U(t, s)x = S(t - s)x + \int_s^t S(t - \xi)f(\xi, U(\xi, s)x, g_\xi)d\xi, \quad (10) \]

\[ V(t, s)x = S(t - s)x + \int_s^t S(t - \xi)f(\xi, V(\xi, s)x, h_\xi)d\xi, \quad (11) \]

for given \( g, h \in AP(X), x \in X, t \geq s. \)
Putting \( u(t) = U(t,s)x, v(t) = V(t,s)x \) for given \( s, x \), from the assumptions we have
\[
[u(t) - v(t), f(t, u(t), g_t) - f(t, v(t), h_t)] \leq m(t, \|u(t) - v(t)\|),
\]
where \( m(t, \|u(t) - v(t)\|) = \gamma \|u(t) - v(t)\| + \delta \|h - g\| \). Using this we get
\[
\|u(t) - v(t)\| \leq \|u(t - \eta) - v(t - \eta)\| + \eta m(t, \|u(t) - v(t)\|) + \int_{t-\eta}^t \|S(t - \xi)f(\xi, u(\xi), h_\xi) - f(t, u(t), h_t)\| d\xi + \int_{t-\eta}^t \|S(t - \xi)f(\xi, v(\xi), g_\xi) - f(t, v(t), g_t)\| d\xi.
\]
Now let us fix arbitrary real numbers \( a \leq b \). Since the functions \( S(t - \xi)f(\xi, u(\xi), h_\xi) \) and \( S(t - \xi)f(\xi, v(\xi), g_\xi) \) are uniformly continuous on the set \( a \leq \xi \leq b \), for every \( \epsilon > 0 \) there exists an \( \eta_0 = \eta_0(\epsilon) \) such that
\[
\|S(t - \xi)f(\xi, u(\xi), h_\xi) - f(t, u(t), h_t)\| < \epsilon,
\]
\[
\|S(t - \xi)f(\xi, v(\xi), g_\xi) - f(t, v(t), g_t)\| < \epsilon,
\]
for all \( \|t - \xi\| < \eta_0 \) and \( t \leq \xi \in [a, b] \). Hence, denoting \( \|u(t) - v(t)\| \) by \( \alpha(t) \), for \( \eta < \eta_0 \) we have
\[
\alpha(t) - e^{\omega \eta} \alpha(t - \eta) \leq \eta m(t, \alpha(t)) + 2\eta \epsilon.
\]
Applying this estimate repeatedly, we get
\[
\alpha(t) - e^{\omega (t-s)} \leq \sum_{i=1}^{n} e^{\omega (t-t_i)} m(t_i, \alpha(t_i)) \Delta_i + 2 \epsilon \sum_{i=1}^{n} e^{\omega (t-t_i)} \Delta_i,
\]
where \( t_0 = s < t_1 < t_2 < ... < t_n = t \) and \( |t_i - t_{i-1}| = \Delta_i \). Thus, since \( \epsilon \) is arbitrary, and since the function \( m \) is continuous, we get
\[
\alpha(t) - e^{\omega (t-s)} \alpha(s) \leq \int_s^t e^{\omega (t-\xi)} m(\xi, \alpha(\xi)) d\xi
\]
\[
= \int_s^t e^{\omega (t-\xi)} (\gamma \alpha(\xi) + \delta \|h - g\|) d\xi.
\]
Applying Gronwall’s inequality we get
\[
\alpha(t) \leq e^{(\gamma + \omega) (t-s)} \alpha(s) + e^{\gamma (t-s) + \omega t} \left( \frac{e^{-\omega s} - e^{-\omega t}}{\omega} \right) \delta \|h - g\|.
\]
Because of the identity \( \alpha(s) = \|u(s) - v(s)\| = \|U(s, s)x - V(s, s)x\| = 0 \), from the above estimate we obtain
\[
\sup_{t-1 \leq \xi \leq t} \|U(\xi, t-1)x - V(\xi, t-1)x\| \leq \frac{e^{\gamma + \omega} - e^{\gamma}}{\omega} \delta \|h - g\|.
\]
Now let us denote by \( T_h^t, T_g^t, t \geq 0 \) the respective evolution semigroups corresponding to equations (10) and (11). Since \( Th \) and \( Tg \) are defined as the
unique fixed points \( u_0, v_0 \) of \( T_h, T_g \), respectively, we have
\[
\|T_h - T_g\| = \|u_0 - v_0\| = \|T_h u_0 - T_g v_0\| + \|T_g u_0 - T_h v_0\| \\
\leq \frac{e^{\gamma + \omega} - e^{\gamma}}{\omega} \delta \|h - g\| + e^{\omega - \mu} \|u_0 - v_0\| \\
= N \delta \|h - g\| + e^{\omega - \mu} \|T_h - T_g\|,
\]
where \( N = (e^{\gamma + \omega} - e^{\gamma})/\omega \). Finally, we have
\[
\|T_h - T_g\| \leq \frac{e^{\gamma}(e^\omega - 1)}{\omega(1 - e^{\omega - \mu})}.
\]
Thus, if the estimate
\[
\delta < \frac{\omega(1 - e^{\omega - \mu})}{e^{\gamma}(e^\omega - 1)} \tag{13}
\]
holds true, then \( T \) is a strict contraction mapping in \( AP(X) \). By virtue of the Contraction Mapping Principle \( T \) has a unique fixed point. It is easy to see that this fixed point is an almost periodic mild solution of equation (1). This completes the proof of the theorem. 

Remarks. 1) In case \( \omega = 0, \gamma = -\mu \) we get the estimate
\[
\delta < e^\mu - 1 = \mu + \mu^2/2 + ...
\]
which guarantees the existence of the fixed point of \( T \).

2) If \( \omega + \gamma < 0 \), then we can choose \( \mu = -\gamma \), and therefore we get the accretiveness condition on \(- (F_* + \mu I)\). However, in general, the condition \( \omega + \gamma < 0 \) is a very strong restriction on the coefficients of equation (1), if \( f \) depends explicitly on \( t \).

4. Examples

In applications one frequently encounters functions \( f \) from \( \mathbb{R} \times X \times C \rightarrow X \) of the form
\[
f(t, x, g_t) = F(t, x) + G(t, g_t), \ \forall t \in \mathbb{R}, \ x \in X, \ g_t \in C,
\]
where \( F \) satisfies condition ii) of Definition 5 and \( G(t, y) \) is Lipschitz continuous with respect to \( y \in C \), i.e.
\[
\|G(t, y) - G(t, z)\| \leq \delta \|y - z\|, \ \forall t \in \mathbb{R}, \ y, z \in C
\]
for some positive constant \( \delta \). With \( f \) in this form numerous examples of partial functional differential equations fitting into our abstract framework can be found (see e.g. [2], [18], [19], [26], [27], in particular the recent book by Wu [35]).

In order to describe a concrete example we consider a bounded domain \( \Omega \) in \( \mathbb{R}^n \) with smooth boundary \( \partial \Omega \) and suppose that
\[
A(x, D)u = \sum_{|\alpha| \leq 2m} a_\alpha(x)D^\alpha u
\]
is a strongly elliptic differential operator in $\Omega$. Then, defining the operator

$$ Au = A(x, D)u, \forall u \in D(A) = W^{2m,2}(\Omega) \cap W^{m,2}_0(\Omega) $$

we know from [27, Theorem 3.6] that the operator $-A$ is the infinitesimal generator of an analytic semigroup of contractions on $L^2(\Omega)$. Now let $f, g : \mathbb{R} \times \Omega \times \mathbb{R} \to \mathbb{R}$ be Lipschitz continuous and define the operators $F(t, w)(x) = f(t, x, w(x))$ and $G(t, w)(x) = g(t, x, w(x))$ where $t \in \mathbb{R}$, $x \in \Omega$ and $w \in L^2(\Omega)$. Then, for any positive constant $r$, the boundary value problem

$$ \frac{\partial u(t, x)}{\partial t} = A(x, D)u(t, x) + f(t, x, u(t, x)) + g(t, x, u(t-r, x)) \quad \text{in} \ \Omega, $$

$$ u(t, x) = 0 \quad \text{on} \ \partial \Omega $$

fits into the abstract setting of equation (1).

**Acknowledgement.** This work has been carried out while the second author (N.V.M.) was a fellow of the Alexander von Humboldt Foundation. The assistance of the Foundation is gratefully acknowledged. N.V.M. thanks Professors B. Aulbach, R. Nagel, F. Räbiger and the Division of Functional Analysis of the Institute of Mathematics, University of Tübingen, for hospitality, useful discussions and encouragement. N.V.M. also thanks Professor G. Webb for useful suggestions and encouragement. Finally, the authors thank the referee for useful comments leading to an improvement of the original version of this paper.

Mathematical Problems in Engineering

Special Issue on
Modeling Experimental Nonlinear Dynamics and
Chaotic Scenarios

Call for Papers

Thinking about nonlinearity in engineering areas, up to the 70s, was focused on intentionally built nonlinear parts in order to improve the operational characteristics of a device or system. Keying, saturation, hysteretic phenomena, and dead zones were added to existing devices increasing their behavior diversity and precision. In this context, an intrinsic nonlinearity was treated just as a linear approximation, around equilibrium points.

Inspired on the rediscovering of the richness of nonlinear and chaotic phenomena, engineers started using analytical tools from “Qualitative Theory of Differential Equations,” allowing more precise analysis and synthesis, in order to produce new vital products and services. Bifurcation theory, dynamical systems and chaos started to be part of the mandatory set of tools for design engineers.

This proposed special edition of the Mathematical Problems in Engineering aims to provide a picture of the importance of the bifurcation theory, relating it with nonlinear and chaotic dynamics for natural and engineered systems. Ideas of how this dynamics can be captured through precisely tailored real and numerical experiments and understanding by the combination of specific tools that associate dynamical system theory and geometric tools in a very clever, sophisticated, and at the same time simple and unique analytical environment are the subject of this issue, allowing new methods to design high-precision devices and equipment.

Authors should follow the Mathematical Problems in Engineering manuscript format described at http://www.hindawi.com/journals/mpe/. Prospective authors should submit an electronic copy of their complete manuscript through the journal Manuscript Tracking System at http://mts.hindawi.com/ according to the following timetable:

<table>
<thead>
<tr>
<th>Manuscript Due</th>
<th>February 1, 2009</th>
</tr>
</thead>
<tbody>
<tr>
<td>First Round of Reviews</td>
<td>May 1, 2009</td>
</tr>
<tr>
<td>Publication Date</td>
<td>August 1, 2009</td>
</tr>
