ABSTRACT. In the present work, two complex inversion formulas of Byrne and Love for generalized Stieltjes transformation are shown to be valid for a class of distributions. This is accomplished by transferring the complex inversion formulas on the testing function space of a class of distributions and then showing that the limiting process in the resulting formula converges in the topology of the testing function space.

KEY WORDS AND PHRASES. Generalized Functions, Stieltjes Transformation.

1. INTRODUCTION.

Let \( p \) be any complex number except zero and the negative integers. Then
for all \( s \) in the "cut plane", that is all complex numbers except those which are negative real or zero, the Stieltjes Transform in its general form is defined by:

\[
F(s) = \int_0^\infty \frac{f(t)dt}{t + s} \tag{1.1}
\]

The following inversion theorems for particular values of \( p \) and \( s \) are well known.

**THEOREM A (Widder).** If \( f(t) \) belongs to \( L(0,R) \) for every positive \( R \) and is such that the integral

\[
F(x) = \int_0^\infty \frac{f(t)dt}{t + x}
\]

converges for \( x > 0 \), then \( F(s) \) exists for complex \( s \) in the cut plane and

\[
\lim_{\eta \to 0^+} \frac{f(-\xi-i\eta)-f(-\xi+i\eta)}{2\pi i} = \frac{f(\xi^+)+f(\xi^-)}{2}
\]

for any positive \( \xi \) at which \( f(\xi^+) \) and \( f(\xi^-) \) both exist.

**THEOREM B (Summer).** If \( p > 0 \), \( f(t) \) is locally integrable in \([0,\infty]\), the improper Lebesgue integral.

\[
F(s) = \int_0^\infty \frac{f(t)dt}{t + s} \tag{1.1}
\]

converges (for a certain value of \( s \) in the cut plane and so for all), \( t > 0 \) and the limits \( f(t+0) \) exist, then:

\[
\frac{1}{2} [f(t+0)+f(t-0)] = \lim_{\eta \to 0^+} \left[ \frac{1}{2\pi i} \int_0^\infty dx \int_0^C \frac{F'(x)dz}{(x+z)^{P+1}} \right]
\]
where $C_\eta$ is a contour in the cut plane from $-x-i\eta$ to $-x+i\eta$.

**THEOREM 1.3 (Byrne and Love).** If $\Re p > 1$, $f$ is locally integrable in $[0, \infty]$, improper Lebesgue integral (1.1) converges, and $\lambda > 0$; then, for each positive $x$ for which the Lebesgue limits $f(x+0)$ exists,

$$\frac{1}{2} \left(f(x+0) + f(x-0)\right) = \lim_{\eta \to 0^+} \frac{p-1}{2\pi i} \int_{-x}^{\lambda} (x+t)^{p-2} \left[F(t-i\eta) - F(t+i\eta)\right] dt. \quad [2, p. 349]$$

**THEOREM 1.4 (Byrne and Love).** If $\Re p > 1$, $\frac{f(t)}{1+t^2} \in L(0, \infty)$ and the improper Lebesgue integral

$$F(s) = \int_0^\infty \frac{f(t)}{(s+t)^p} dt$$

converges, then for each positive $x$ for which the Lebesgue limit $f(x+0)$ exists,

$$\frac{1}{2} \left[f(x+0) + f(x-0)\right] = \lim_{\eta \to 0^+} \int_{-x}^{\infty} (x+t)^{p-2} \left[F(t-i\eta) - F(t+i\eta)\right] dt \quad [2, p. 352]$$

**THEOREM 1.1** has been extended to distributions by Pandey and Zemanian [13] and Pandey [14]. Theorem 1.2 was extended to distribution by Pathak [15]. Our object is to extend theorems 1.3 and 1.4 of Byrne and Love to generalized functions (distributions).

2. **THE TESTING FUNCTION SPACE, $S_0(I)$ AND ITS DUAL.**

An infinitely differentiable complex valued function $\xi(x)$ defined over $I = (0, \infty)$ belongs to the testing function spaces $S_0(I)$ if,

$$\gamma_k(\xi) = \sup_{0 < x < \infty} \left|(1+x)^\alpha x^k \left(\frac{d}{dx}\right)^k \xi(x)\right| < \infty$$
for all \( k = 0, 1, 2, \ldots \), where \( \alpha \) is a fixed real number. Clearly, \( S_\alpha(I) \) is a vector space with respect to the field of complex numbers. The zero element of the vector space \( S_\alpha(I) \) is the function defined over \( I \) which is identically zero. The topology over \( S_\alpha(I) \) is generated by the collection of seminorms 
\([\gamma_k]_{k=0}^\infty [24; \text{p. 8}]. \) We say that a sequence \( \{\xi_{\nu}\} \) where \( \xi_{\nu} \) belongs to \( S_\alpha(I) \) converges in \( S_\alpha(I) \) to \( \xi(x) \) if for each fixed \( k, \gamma_k(\xi_{\nu} - \xi) \) tends to zero as \( \nu \) tends to \( \infty \). The space \( S_\alpha(I) \) is a locally convex Hausdorff topological vector space. The space \( D(I) \) is a vector subspace of \( S_\alpha(I) \) and the topology of \( D(I) \) is stronger than the topology induced on \( D(I) \) by \( S_\alpha(I) \) and as such the restriction of any member of \( S'_\alpha(I) \) to \( D(I) \) is in \( D'(I) \), where \( S'_\alpha(I) \) and \( D'(I) \) denote the dual spaces of \( S_\alpha(I) \) and \( D(I) \) respectively. We say that a sequence \( \{\xi_{\nu}\} \) where \( \xi(x) \) belongs to \( S_\alpha(I) \) is a Cauchy sequence in \( S_\alpha(I) \) if \( \gamma_k(\xi_{\nu} - \xi) \) goes to zero for any non-negative integer \( k \) as \( \mu \) and \( \nu \) both tend to infinity independently of each other. It can be readily seen that \( S_\alpha(I) \) is sequentially complete.

3. THE DISTRIBUTIONAL STIETJES TRANSFORMATION

For a complex \( s \) not negative or zero, \( \frac{1}{(s+x)^p} \) belongs to \( S'_\alpha \) where \( a < \text{Re} \, p \). Therefore, the distributional Stieltjes transformation \( F(s) \) of an arbitrary element \( f \in S'_\alpha, \ a < \text{Re} \, p \), is defined by

\[
F(s) \triangleq \frac{1}{(s+x)^p} < f(x) > \tag{3.1}
\]

where \( s \) belongs to the complex plane cut along the negative real axis including the origin.

THEOREM 3.1. If \( m \) and \( k \) both assume non-negative integral values and \( \Omega \) is a
compact set of the complex plane not meeting the negative real axis, then for fixed non-negative integers \( m \) and \( k \), there exists a constant \( B \) satisfying

\[
\gamma_m \left[ \frac{1}{(s+x)^{p+k}} \right] \leq B \Omega < \infty
\]

uniformly for all \( s \) lying in the compact set \( \Omega \) of the complex plane not meeting the negative real axis on the origin.

**Proof.** Using the compactness of the set \( \Omega \) and the fact that \( \frac{1}{(s+x)^{p+k}} \in S'_{\alpha} \), \( \alpha < \Re p \), the theorem is immediate.

**Theorem 3.2.** For an arbitrary \( f \in S'_\alpha \) and \( \alpha < \Re p \) let \( F(s) \) be defined by the equation (3.1). Then, for \( m = 1, 2, \ldots \)

\[
\left( \frac{d}{ds} \right)^m F(s) = \langle f(x), \frac{(-1)^m(p)^m}{(s+x)^{p+m}} \rangle
\]

where \( (p)_m = p(p+1)(p+2) \ldots (p+m-1) \).

**Proof.** If \( p \) is such that \( s^p \) does not have a branch cut in the complex plane, the proof can be given in a way similar to that given in [3, Lemma 2a]. If \( p \) is such that \( s^p \) has a branch cut (along the negative real axis for the sake of definiteness), then choose the contour of integration as shown in the complex-plane cut along the negative real axis below.
Here, $C_1$ and $C_2$ are arcs of two concentric circles with centre at origin and $C$ is the contour of integration as shown. The radii of $C_1$ and $C_2$ and paths $L_1$ and $L_2$ are so chosen that the point $s$ is contained in the region bounded by the contour.

Let $d = \inf_{\xi \in C} |\xi - s|$ and choose $|\Delta s| < \frac{d}{2}$. Now

$$\lim_{\Delta s \to 0} \frac{F(s+\Delta s) - F(s)}{\Delta s} = \left< f(t), \frac{1}{(s+t)^{p+1}} \right>$$

$$= \left< f(t), \frac{1}{\Delta s} \cdot \frac{1}{2\pi i} \int_C \frac{1}{(z+t)^p} \left[ \frac{1}{z-s-\Delta s} - \frac{1}{z-s} - \frac{\Delta s}{(z-s)^2} \right] dz \right>$$

where $C$ is the contour shown in the diagram

$$= \left< f(t), \theta_{\Delta s} \right>$$

where

$$\theta_{\Delta s} = \frac{\Delta s}{2\pi i} \int_C \frac{1}{(z+t)^p} \frac{1}{(z-s)^p(z-s-\Delta s)} dz$$

We now wish to show that $\theta_{\Delta s} \to 0$ in $S(\alpha)$ as $\Delta s \to 0$.

Using Theorem 3.1, we have

$$\gamma_k(\theta_{\Delta s}) \leq B_\epsilon \frac{|\Delta s|}{2\pi} \frac{L}{d^3},$$

(3.4)
where $L$ is the length of the contour $C$ and $B_c$ is the uniform bound of

$$
\frac{(p)_k(t+t)^{\alpha t^k}}{(z+t)^{p+k}}
$$

for all $z$ lying on the closed contour $C$ and $t > 0$.

Letting $\Delta s \to 0$ in (3.3) and using (3.4), we get

$$
F'(s) = \langle f(t), \frac{P}{(s+t)^{p+1}} \rangle
$$

Now, the theorem follows from induction on the order of the derivative of $F(s)$.

**Theorem 3.3.** The function $F^{(m)}(x)$ for real $x$ where $F(s)$ is the Stieltjes transform of $f \in S^\alpha$, satisfies the following relation:

$$
F^{(m)}(x) = \begin{cases} 
0[x^{-m}] & \text{as } x \to \infty \text{ if } \alpha < \text{Re } p \\
0[x^{-k}] & \text{as } x \to \infty \text{ if } \alpha = \text{Re } p \\
0[x^{-k-\text{Re } p}] & \text{as } x \to 0 \text{ if } \alpha \leq \text{Re } p
\end{cases}
$$

The proof is immediate from the boundedness property of distributions [9, p. 18].

4. **Complex Inversion Theorems**

We are now ready to prove our first inversion theorem.

**Theorem 4.1.** For a fixed $\alpha < 1$ and $\text{Re } p > 1$, let $f \in S^\alpha(I)$ and let $F(s)$ be the Stieltjes transform of $f(t)$ as defined by (3.1). Then,

$$
\lim_{\eta \to 0} \frac{p-1}{2\pi i} \int_{-\infty}^{\infty} (x+t)^{p-2} [F(t-i\eta) - F(t+i\eta)] dt, \xi(x) > \langle f, \xi \rangle = \langle f, \xi \rangle_{\omega r} : \xi \in D(I)
$$

**Proof.** First consider

$$
\int_{-\infty}^{\infty} (x+t)^{p-2} F(t-i\eta) dt = \int_{-\infty}^{\infty} (x+t)^{p-2} f(y), \frac{1}{(y+t-i\eta)^p} > dt \quad (4.1)
$$
For fixed $x$ and $t$,
\[
\frac{(x+t)^{p-2}}{(y+t-i\eta)^p} \in S(\alpha).
\]

Since, in view of Theorem 3.2, $F(s)$ is analytic in the cut plane, the left-hand side integral in (4.1) is meaningful. By using the technique of Riemann sums it can be shown that for $\varepsilon > 0$,
\[
\lambda \int_{-x-\varepsilon}^x (x+t)^{p-2} F(t-i\eta) dt = \left< f(y), \int_{-x-\varepsilon}^x \frac{(x+t)^{p-2}}{(y+t-i\eta)^p} dt \right>
\]
\[
= \left< f(y), \frac{1}{p-1} \cdot \frac{1}{(x-y+i\eta)^p} \left[ \frac{(x^+\lambda)^{p-1}}{(y^+\lambda-i\eta)^{p-1}} - \frac{\varepsilon^{p-1}}{(y-x+i\eta)^{p-1}} \right] \right>
\]
\[
= I \text{ (say).}[\text{by Lemma 5.1, p. 333}]
\]

One can easily check that as $\varepsilon \to 0+$, $\frac{\varepsilon^{p-1}}{(y-x+i\eta)^{p-1}} \to 0$ in $S(\alpha)$ for $\Re p > 1 > \alpha$ and for fixed $\lambda, \eta$ and $x$. Therefore, letting $\varepsilon \to 0$, we get:
\[
\lambda \int_{-x}^x (x+t)^{p-2} F(t-i\eta) dt = \left< f(y), \frac{\theta^+\lambda)^{p-1}}{(p-1)(y-x+i\eta)(y^+\lambda-i\eta)^{p-1}} \right>
\]
\[
(4.2)
\]

In view of Lemma 3.5* [7, p. 12], it follows that: as $\lambda \to \infty$
\[
\frac{1}{(y-x-i\eta)} \left( \frac{\lambda+x}{(y^+\lambda-i\eta)} \right)^{p-1} \to \frac{1}{y-x-i\eta} \text{ in } S(\alpha)
\]
\[
(4.3)
\]

for fixed $x$ and $\eta$.

Therefore, letting $\lambda \to \infty$ in (4.2), we obtain
\[
\int_{-x}^x (x+t)^{p-2} F(t-i\eta) dt = \left< f(y), \frac{1}{p-1} \cdot \frac{1}{y-x-i\eta} \right>
\]
\[
(4.4)
\]

* The proof was provided by Professor E.R. Love.
Using a similar argument, we can show that

\[
\int_{-\infty}^{\infty} (x+t)^{p-2} F(t+i\eta) dt = \langle f(y), \frac{1}{p-1} \cdot \frac{1}{y-x+i\eta} \rangle
\]  

Combining Equations (4.4) and (4.5), we get

\[
\int_{-\infty}^{\infty} (x+t)^{p-2} [F(t-i\eta) - F(t+i\eta)] dt
\]

\[
= \langle f(y), \frac{\eta}{\pi [(y-x)^2 + \eta^2]} \rangle
\]  

Now using the technique of Riemann sums, we obtain

\[
\int_{-\infty}^{\infty} (x+t)^{p-2} [F(t-i\eta) - F(t+i\eta)] dt, \xi(x)
\]

\[
= \langle f(y), \int_a^b \frac{\eta \xi(x) dx}{\pi [(y-x)^2 + \eta^2]} \rangle
\]  

where the support of \( \xi(x) \in D(I) \) is contained in \((a,b), b > a > 0\). Using the same techniques as followed in proving Theorem 2 of (3) one can show that

\[
\lim_{\eta \to 0+} \int_a^b \frac{\eta \xi(x) dx}{\pi [(y-x)^2 + \eta^2]} \to \xi'(y)
\]  

in the topology of \( S(I) \) as \( \eta \to 0+ \). Therefore, letting \( \eta \to 0+ \) in (4.7), we have

\[
\lim_{\eta \to 0+} \int_{-\infty}^{\infty} (x+t)^{p-2} [F(t-i\eta) - F(t+i\eta)] dt, \xi(x) = \langle f, \xi \rangle
\]

This completes the proof of the theorem.

To prove our other inversion theorems, we require a couple of Lemmas.

**Lemma 4.2.** Let \( t, s, \eta > 0 \). Then, for finite \( b > a > 0 \) and \( \alpha < 1 \),

\[
\lim_{\eta \to 0+} \int_a^b \frac{|t-x|}{\eta} \frac{1}{(t-x)^2 + \eta^2} dx = 0
\]

uniformly for all \( x > 0 \).
PROOF. Let
\[ I = (1+x)^\alpha \int_a^b \frac{|t-x|}{(t-x)^2 + \eta^2} \, dt \]

Since \( \sup_{x > N, b < t < a} (1+x)^\alpha \frac{|t-x|}{(t-x)^2 + \eta^2} \) is bounded, for \( \varepsilon > 0 \), there exists a positive \( N > b \) and \( 0 < q < 1 \) such that

\[ |I| < \varepsilon \] \hspace{1cm} (4.9)

uniformly for all \( x \in (0, q) \) and \( x > N \).

Now assume that \( \delta \) is a positive number \( \leq \min \left( 1, \frac{a}{2} \right) \) and for \( \delta \leq x \leq N \) let us write.

\[ I = (1+x)^\alpha \int_a^{a+x-\delta} \frac{|t-x|}{(t-x)^2 + \eta^2} \, dt + \int_{a+x-\delta}^{a+x+\delta} \frac{|t-x|}{(t-x)^2 + \eta^2} \, dt + \int_{a+x+\delta}^b \frac{|t-x|}{(t-x)^2 + \eta^2} \, dt. \] \hspace{1cm} (4.10)

Denote the three expressions on the right-hand side of Eqn. (4.10) by \( I_1, I_2 \) and \( I_3 \) respectively.

Now

\[ I_2 = \eta \int_{a+x-\delta}^{a+x+\delta} \frac{|t-x|}{(t-x)^2 + \eta^2} \, dt \]

\[ \leq \eta \frac{1}{2\eta} \frac{2\delta}{(1+N)^\alpha} = \delta (1+N)^\alpha \]

Now choose \( \delta \) such that \( \delta (1+N)^\alpha < \varepsilon \) and fix \( \delta \) this way. Therefore

\[ |I_2| < \varepsilon \] \hspace{1cm} (4.11)

uniformly for all \( x \in [\delta, N] \) and \( \eta \in [0, q] \).

\[ I_3 = \eta \int_{a+x+\delta}^b \frac{(1+x)^\alpha |t-x|}{(t-x)^2 + \eta^2} \, dt = (1+x)^\alpha \eta \left[ \int_a^x + \int_{a+x+\delta}^b \frac{|t-x|}{(t-x)^2 + \eta^2} \, dt \right] \]
Therefore,

\[ I_3 = \begin{cases} \frac{\pi}{2} \ln \left( \frac{(b-x)^2 + \eta^2}{(a+x)^2 + \eta^2} \right) (1+x)^\alpha, & \text{if } \delta < x < b \\ \frac{(1+x)^\alpha}{2} \ln \left( \frac{\eta}{[(a+x)^2 + \eta^2] [(b-x)^2 + \eta^2]} \right) & \text{if } x \geq b. \end{cases} \]

Therefore, \( I_3 \to 0 \) as \( \eta \to 0^+ \) uniformly for all \( x \in [\delta, N] \).

Next,

\[ I_1 = (1+x)^\alpha \eta \int_a^{a+x-\delta} \frac{|t-x| dt}{(t-x)^2 + \eta^2} \]

Now for \( \delta \leq x \leq a \)

\[ I_1 = (1+x)^\alpha \frac{\pi}{2} \ln \left( \frac{(a-x)^2 + \eta^2}{(a-x)^2 + \eta^2} \right) \to 0 \text{ as } \eta \to 0^+ \] (4.13)

uniformly for all \( x \) lying in \([\delta, a]\).

For \( a \leq x \leq N \),

\[ I_1 = \left[ -\frac{\pi}{2} \ln \left( \frac{\eta^2}{(a-x)^2 + \eta^2} \right) \right]^{(1+x)^\alpha} \]

\( \to 0 \text{ as } \eta \to 0^+ \) uniformly for all \( x \in [a, N] \) (4.14)

Combining results (4.11) through (4.14) we have

\[ \lim_{\eta \to 0^+} |I| \leq \epsilon \text{ uniformly for all } x \geq 0 \] (4.15)

Now, for \( 0 < x \leq \delta \), we can see that

\[ |I| \leq (1+x)^\alpha \eta \ln \left[ \frac{(b-x)^2 + \eta^2}{(a-x)^2 + \eta^2} \right] \to 0 \] (4.16)

As \( \eta \to 0^+ \) uniformly for all \( x \in [0, \delta] \).
Combining results (4.15) and (4.16), we get
\[ \lim_{\eta \to 0^+} |I| \leq \epsilon \quad \text{uniformly for all } x > 0. \]
Thus, the proof of the lemma is complete.

**Lemma 4.3.** Let \( \Re p > 1 > \alpha \). Assume that \( t, x, \lambda \) and \( \eta \) are all positive numbers and \( \xi(t) \in D(1) \). Then,
\[
I(x,t) = \frac{1}{2\pi i} \int_{a}^{b} \left\{ \frac{1}{x-t+i\eta} \left[ \left( \frac{t+\lambda}{x+\lambda+i\eta} \right)^{p-1} - 1 \right] \right\} \xi(t) dt \to 0
\]
as \( \eta \to 0^+ \) in the topology of \( S_{\alpha} \) where the support of \( \xi(t) \in D(1) \) is contained in \((a,b); \ b > a > 0\).

**Proof.** We have to show that for each \( m = 0, 1, 2, \ldots \) \( (1+x)^{\alpha} x^m D_x I(x, \eta) \to 0 \) as \( \eta \to 0 \) uniformly.

It can be easily shown that
\[
D_x^m I(x, \eta) = 0 \left( \frac{1}{x^{m+1}} \right) \quad \text{as } x \to \infty
\]
uniformly for all \( \eta \) satisfying \( 0 < \eta < 1 \). So,
\[
(1+x)^{\alpha} x^m D_x I(x, \eta) \to 0 \quad \text{as } x \to \infty
\]
uniformly for all \( \eta \in (0,1) \). Therefore, for \( \epsilon > 0 \) there exists \( N > 0 \) such that
\[
\left| (1+x)^{\alpha} x^m D_x I(x, \eta) \right| < \epsilon \quad \text{(4.17)}
\]
uniformly for all \( x \geq N \), and \( 0 < \eta < 1 \).

Now consider the case \( 0 < x \leq \eta \). We will first give the proof for \( m = 0 \) and complete the proof for \( m = 1, 2, 3, \ldots \) by using the result for the case \( m = 0 \).
I. For \( m = 0 \). Write

\[
(1+x)^\alpha I(x, \eta) = \frac{(1+x)^\alpha}{2\pi i} \int_a^b \frac{x-t}{(x-t)^2 + \eta^2} \left[ \left( \frac{t-h}{x+h+i\eta} \right)^{p-1} - \left( \frac{t+h}{x-h-i\eta} \right)^{p-1} \right] \xi(t) dt
\]

\[
- (1+x)^\alpha \eta \int_a^b \frac{\xi(t)}{(x-t)^2 + \eta^2} \left[ \left( \frac{t+h}{x+h+i\eta} \right)^{p-1} - 1 + \left( \frac{t-h}{x-h-i\eta} \right)^{p-1} - 1 \right] \xi(t) dt
\]

\[= I_1(x, \eta) - I_2(x, \eta) \] (say)

First, consider \( I_1(x, \eta) \). Since,

\[
\left| \frac{1}{(x+h+i\eta)^{p-1}} - \frac{1}{(x-h-i\eta)^{p-1}} \right| = \left| (p-1) \int_{\eta}^{\infty} z^{p-1} \right|
\]

\[
\leq 2|p-1| \eta e^{\pi} |\text{Im } p| / \lambda \text{Re } p
\]

Therefore we can find a constant \( B(p) \) independent of \( x \) and \( \eta \) such that

\[|I_1(x, \eta)| \leq B(1+x)^\alpha \eta \int_a^b \frac{|x-t|dt}{(x-t)^2 + \eta^2}
\]

In view of Lemma 4.2, the right-hand side converges to 0 uniformly for all \( x > 0 \) as \( \eta \to 0^+ \).

We now consider \( I_2(x, \eta) \). For \( 0 < \eta < b \), using Lemma 3.3 (7, p. 9) we get

(1) For \( \text{Re } p \geq 2 \), \( t \leq x \)

\[
\left| \left( \frac{t-h}{x+h+i\eta} \right)^{p-1} - 1 \right| \leq |p-1|e^{2\pi} |\text{Im } p| \frac{|t-x|+\eta}{\sqrt{(x+h)^2+\eta^2}} , \quad t \leq x
\]

\[
\leq |p-1|e^{2\pi} |\text{Im } p| \frac{|t-x|+\eta}{\lambda} ,
\] (4.18)
(ii) For \( \text{Re} \, p \geq 2, \ t \geq x \)

\[
\left| \left( \frac{t+\lambda}{x+\lambda+i\eta} \right)^{p-1} - 1 \right| \leq \frac{|p-1|e^{2\pi|\text{Im} \, p|}}{\text{Re} \, p-1} \left( \frac{|t-x|+\eta}{(a+b)^2+\eta^2} \right)^{2-\text{Re} \, p} \cdot \left( \frac{|t-x|+\eta}{(a+b)^2+\eta^2} \right)^{2-\text{Re} \, p} \text{Re} \, p-2 \quad (4.19)
\]

(iii) For \( \text{Re} \, p \leq 2, \ t \leq x \) and \( t \in [a,b], \ b > a > 0, \ 0 < \eta < 1 \)

\[
\left| \left( \frac{t+\lambda}{x+\lambda+i\eta} \right)^{p-1} - 1 \right| \leq \frac{|p-1|e^{2\pi|\text{Im} \, p|}}{\text{Re} \, p-1} \left[ \frac{1}{(1+\lambda)^2} \right]^{\text{Re} \, p-2} \cdot \left( \frac{|t-x|+\eta}{(a+b)^2+\eta^2} \right)^{2-\text{Re} \, p-2} \text{Re} \, p-2 \quad (4.20)
\]

(iv) For \( \text{Re} \, p \leq 2, \ t \geq x, \ t \in [a,b], \ b > a > 0, \ 0 < \eta < 1 \)

\[
\left| \left( \frac{t+\lambda}{x+\lambda+i\eta} \right)^{p-1} - 1 \right| \leq \frac{|p-1|e^{2\pi|\text{Im} \, p|}}{\lambda} \left[ \frac{1}{1+\lambda^2} \right]^{\text{Re} \, p-2} \left( \frac{|t-x|+\eta}{(x+y)^2+\eta^2} \right)^{2-\text{Re} \, p} \\quad (4.21)
\]

Therefore, from inequalities (4.19) through (4.21), it is evident that for

\( \text{Re} \, p > 1 \) and \( 0 < \eta < 1 \), there exists a positive constant \( K(\lambda,p) \) independent of

\( t \) and \( x \) satisfying

\[
\left| \left( \frac{t+\lambda}{x+\lambda+i\eta} \right)^{p-1} - 1 \right| \leq K(\lambda,p) \left[ (t-x) + \eta \right] \quad t \in (a,b)
\]

Similarly, under the same set of conditions

\[
\left| \left( \frac{t+\lambda}{x+\lambda-i\eta} \right)^{p-1} - 1 \right| \leq K(\lambda,p) \left[ (t-x) + \eta \right], \quad t \in (a,b)
\]

In view of these inequalities we, therefore, have established that
\[
\left| I_2(x, \eta) \right| \leq \frac{K(\alpha, p) M (1+x)\alpha}{\pi} \int_a^b \frac{\eta(t-x) + \eta}{(t-x)^2 + \eta^2} dt
\]

where \( M = \sup_{a \leq t \leq b} |\phi(t)| \)

That is

\[
\left| I_2(x, \eta) \right| \leq \frac{K(\alpha, p) M (1+x)\alpha}{\pi} \left\{ \begin{array}{c}
\int_a^b \frac{|t-x| dt}{(t-x)^2 + \eta^2} + 2 \int_a^b \frac{dt}{(t-x)^2 + \eta^2}
\end{array} \right\}
\]

Since

\[
(1+x)\alpha \eta^2 \int_a^b \frac{dt}{(t-x)^2 + \eta^2} \to 0
\]

as \( \eta \to 0^+ \) uniformly for all \( x > 0 \). Therefore, in view of Lemma 5.2, it follows that

\( I_2(x, \eta) \to 0 \) as \( \eta \to 0^+ \) uniformly for all \( x > 0 \).

II) The case \( m = 1, 2, 3, \ldots \)

A careful computation along with integration by parts will show that

\[
(1+x)\alpha x^D_x I(x, \eta) = \frac{(1+x)\alpha}{2\pi i} \int_a^b \left\{ \frac{1}{x-t+i\eta} \left[ \left( \frac{x+t+i\eta}{x+t+i\eta} \right)^{p-1} - 1 \right] \right\} \phi'(t) dt
\]

\[
+ \frac{(p-1)}{2\pi i} (1+x)\alpha x^D_x \int_a^b \left[ (x+t+i\eta)^{-p} - (x+t+i\eta)^{-p} \right] (t+x)^{p-2} \phi(t) dt
\]

Using the technique of induction, we obtain:

\[
(1+x)\alpha x^D_x I(x, \eta) = \frac{(1+x)\alpha x^{-m}}{2\pi i} \int_a^b \left\{ \frac{1}{x-t+i\eta} \left[ \left( \frac{x+t+i\eta}{x+t+i\eta} \right)^{p-1} - 1 \right] \right\} \phi^{(m)}(t) dt
\]
\begin{align*}
+ \cdots \\
+ \frac{(1+x)^{\alpha x}}{2\pi i} \int_a^b [((x+i\eta)^p - (x-i\eta)^p] (x+i\eta)^{p-2} \phi^{(m-1)}(t) dt \\
- \frac{p(p-1)}{2\pi i} \frac{(1+x)^{\alpha x}}{2\pi i} \int_a^b [((x+i\eta)^p - (x-i\eta)^p] (x+i\eta)^{p-2} \phi^{(m-2)}(t) dt \\
+ \cdots \\
(-1)^{m-1} \frac{p(p-1) \cdots (p+m-2)}{2\pi i} (1+x)^{\alpha x} x \\
\int_a^b [((x+i\eta)^{p-m+1} - (x-i\eta)^{p-m+1}] (x+i\eta)^{p-2} \phi(t) dt \\
\int_a^b [((x+i\eta)^{p-m+1} - (x-i\eta)^{p-m+1}] (x+i\eta)^{p-2} \phi(t) dt \\
\int_a^b [((x+i\eta)^{p-m+1} - (x-i\eta)^{p-m+1}] (x+i\eta)^{p-2} \phi(t) dt \\
(4.22)
\end{align*}

Denote the integrals on the right-hand side of (5.22) by \( J_1, J_2, \ldots, J_{m+1} \) in that order. In view of case \( m = 0 \), \( J_1 \to 0 \) as \( \eta \to 0+ \) uniformly for all \( x \in (0,N) \).

To show that other integrals converge to 0 as \( \eta \to 0+ \) uniformly for \( x \in (0,N) \), we consider the most general integral \( J_{m+1} \). As before,

\begin{align*}
|((x+i\eta)^{p-m+1} - (x-i\eta)^{p-m+1}| &= |(p-m+1) \int z^{p-m} dz| \\
\leq 2\eta |p+m-1| \frac{\eta |p|}{(x+i\eta)^{p+m}}
\end{align*}

Therefore, we can find a positive constant \( C \) independent of \( x \) and \( \eta \) such that

\begin{align*}
|J_{m+1}| < \eta C \frac{(1+x)^{\alpha x}}{(x+i\eta)^{p+m}} \to 0 \quad \text{as} \quad \eta \to 0+
\end{align*}

uniformly for all \( x \in (0,N) \) and each fixed \( m = 1, 2, \ldots \).

Thus, we have proved that

\begin{align*}
(1+x)^{\alpha x} d^m I(x,\eta) \to 0 \quad \text{as} \quad \eta \to 0+ \quad \text{uniformly for all} \quad x \in (0,N) \quad \text{and each fixed} \quad m = 0, 1, 2, 3, \ldots
\end{align*}

Combining this fact with inequality (4.17), we have

\begin{align*}
\lim_{\eta \to 0+} |(1+x)^{\alpha x} d^m I(x,\eta)| < \epsilon
\end{align*}
uniformly for all $x > 0$ and each fixed $m = 0, 1, 2, \ldots$; since $\epsilon$ is arbitrary our claim is established.

**Theorem 4.4.** Let $\Re p > 1 > \alpha$ and $f(t) \in S'$. If $F(s)$ is the Stieltjes transform of $f(t)$ defined by (3.1) then for $\lambda > 0$ and each $\psi \in D(I)$

$$\lim_{\eta \to 0^+} \frac{p-1}{2\pi i} \int \frac{[F(t+\eta) - F(t+\eta)]}{(t+\eta)^{p-2}} \mathrm{d}t, \quad \psi(t) > 0$$

**Proof.** By using the same technique as used in proving Theorem 4.1, it can be shown that:

$$\frac{p-1}{2\pi i} \int \frac{[F(t+\eta) - F(t+\eta)]}{(t+\eta)^{p-2}} \mathrm{d}t, \quad \psi(t) > 0$$

where the support of $\psi(t)$ is contained in $(a,b)$, $b > a > 0$.

$$= \frac{1}{2\pi i} \int_{a}^{b} \frac{1}{x-t+\eta} \left[ \left( \frac{t+\lambda}{x+\lambda+i\eta} \right)^{p-1} - 1 \right] \frac{1}{x-t+i\eta} \left[ \left( \frac{t+\lambda}{x+\lambda-i\eta} \right)^{p-1} - 1 \right] \frac{1}{x-t-i\eta} \psi(t) \mathrm{d}t. (By \ using \ Riemann's \ sum \ technique)$$

Letting $\eta \to 0^+$, the result follows in view of Lemma 4.3.

**Theorem 4.5.** For a fixed $\alpha < 1 < \Re p$, let $f(t) \in S'(I)$ and let $F(s)$ be the Stieltjes transform of $f(t)$ defined by (3.1). Then,

$$\lim_{\eta \to 0^+} \frac{p-1}{2\pi i} \int_{-\infty}^{\infty} \frac{(t+\eta)^{p-2}}{(x+\eta)^{p-2}} [F(t+\eta) - F(t+\eta)] \mathrm{d}t, \quad \psi(x) > 0$$
for all $\xi \in D(1)$ and $\lambda > 0$.

PROOF. The result follows quite easily in view of Theorems 4.1 and 4.4.

ACKNOWLEDGEMENTS. The authors are grateful to Professor E.R. Love, for his valuable suggestions, in particular for providing the proof of Lemma 4.3. The work of the second author was supported by a National Research Council Grant Number A5298.

Mathematical Problems in Engineering

Special Issue on
Time-Dependent Billiards

Call for Papers

This subject has been extensively studied in the past years for one-, two-, and three-dimensional space. Additionally, such dynamical systems can exhibit a very important and still unexplained phenomenon, called as the Fermi acceleration phenomenon. Basically, the phenomenon of Fermi acceleration (FA) is a process in which a classical particle can acquire unbounded energy from collisions with a heavy moving wall. This phenomenon was originally proposed by Enrico Fermi in 1949 as a possible explanation of the origin of the large energies of the cosmic particles. His original model was then modified and considered under different approaches and using many versions. Moreover, applications of FA have been of a large broad interest in many different fields of science including plasma physics, astrophysics, atomic physics, optics, and time-dependent billiard problems and they are useful for controlling chaos in Engineering and dynamical systems exhibiting chaos (both conservative and dissipative chaos).

We intend to publish in this special issue papers reporting research on time-dependent billiards. The topic includes both conservative and dissipative dynamics. Papers discussing dynamical properties, statistical and mathematical results, stability investigation of the phase space structure, the phenomenon of Fermi acceleration, conditions for having suppression of Fermi acceleration, and computational and numerical methods for exploring these structures and applications are welcome.

To be acceptable for publication in the special issue of Mathematical Problems in Engineering, papers must make significant, original, and correct contributions to one or more of the topics above mentioned. Mathematical papers regarding the topics above are also welcome.

Authors should follow the Mathematical Problems in Engineering manuscript format described at http://www.hindawi.com/journals/mpe/. Prospective authors should submit an electronic copy of their complete manuscript through the journal Manuscript Tracking System at http://mts.hindawi.com/ according to the following timetable:

<table>
