OPTIMAL ORDER YIELDING DISCREPANCY PRINCIPLE FOR SIMPLIFIED REGULARIZATION IN HILBERT SCALES: FINITE-DIMENSIONAL REALIZATIONS

SANTHOSH GEORGE and M. THAMBAN NAIR

Received 13 June 2003

Simplified regularization using finite-dimensional approximations in the setting of Hilbert scales has been considered for obtaining stable approximate solutions to ill-posed operator equations. The derived error estimates using an a priori and a posteriori choice of parameters in relation to the noise level are shown to be of optimal order with respect to certain natural assumptions on the ill posedness of the equation. The results are shown to be applicable to a wide class of spline approximations in the setting of Sobolev scales.

1. Introduction. Many of the inverse problems that occur in science and engineering are ill posed, in the sense that a unique solution that depends continuously on the data does not exist. A typical example of an ill-posed equation that often occurs in practical problems, such as in geological prospecting, computer tomography, steel industry, and so forth, is the Fredholm integral equation of the first kind (cf. [2, 6, 8]). Many such problems can be put in the form of an operator equation \( Ax = y \), where \( A : X \to Y \) is a bounded linear operator between Hilbert spaces \( X \) and \( Y \) with its range \( R(A) \) not closed in \( Y \).

Regularization methods are to be employed for obtaining a stable approximate solution for an ill-posed problem. Tikhonov regularization is a simple and widely used procedure to obtain stable approximate solutions to an ill-posed operator equation (2.1). In order to improve the error estimates available in Tikhonov regularization, Natterer [17] carried out error analysis in the framework of Hilbert scales. Subsequently, many authors extended, modified, and generalized Natterer's work to obtain error bounds under various contexts (cf. Neubauer [18], Hegland [7], Schröter and Tautenhahn [20], Mair [10], Nair et al. [16], and Nair [13, 15]). Finite-dimensional realizations of the Hilbert scales approach has been considered by Engl and Neubauer [3].

If \( Y = X \) and \( A \) itself is a positive selfadjoint operator, then the simplified regularization introduced by Lavrentiev is better suited than Tikhonov regularization in terms of speed of convergence and condition numbers of the resulting equations in the case of finite-dimensional approximations (cf. Schock [19]).

In [4], the authors introduced the Hilbert scales variant of the simplified regularization and obtained error estimates under a priori and a posteriori parameter choice strategies which are optimal in the sense of the “best possible worst error” with respect to certain source set. Recently (cf. [5]), the authors considered a new discrepancy
principle yielding optimal rates which does not involve certain restrictive assumptions as in [4]. The purpose of this paper is to obtain a finite-dimensional realization of the results in [5].

2. Preliminaries. Let $H$ be a Hilbert space and $A : H \to H$ a positive, bounded self-adjoint operator on $H$. The inner product and the corresponding norm are denoted by $\langle \cdot, \cdot \rangle$ and $\| \cdot \|$, respectively. Recall that $A$ is said to be a positive operator if $\langle Ax, x \rangle \geq 0$ for every $x \in H$. For $y \in R(A)$, the range of $A$, consider the operator equation

$$Ax = y. \quad (2.1)$$

Let $\hat{x}$ be the minimal norm solution of (2.1). It is well known that if $R(A)$ is not closed in $H$, then the problem of solving (2.1) for $\hat{x}$ is ill posed in the sense that small perturbations in the data $y$ can cause large deviations in the solution. A prototype of an ill-posed equation (2.1) is an integral equation of the first kind,

$$\int_{0}^{1} k(\xi, t)x(t)dt = y(\xi), \quad 0 \leq \xi \leq 1, \quad (2.2)$$

where $k(\cdot, \cdot)$ is a nondegenerate kernel which is square integrable, that is,

$$\int_{0}^{1} \int_{0}^{1} |k(\xi, t)|^2 dt d\xi < \infty, \quad (2.3)$$

satisfying $k(\xi, t) = k(t, \xi)$ for all $\xi, t$ in $[0, 1]$, and such that the eigenvalues of the corresponding integral operator $A : L^2[0, 1] \to L^2[0, 1],

$$(Ax)(\xi) = \int_{0}^{1} k(\xi, t)x(t)dt, \quad 0 \leq \xi \leq 1, \quad (2.4)$$

are all nonnegative (cf. [14]). For example, one of the important ill-posed problems which arise in applications is the backward heat equation problem: the problem is to determine the initial temperature $\varphi_0 := u(\cdot, 0)$ from the measurements of the final temperature $\varphi_T := u(\cdot, T)$, where $u(\xi, t)$ satisfies

$$u_t - u_{\xi\xi} = 0, \quad (\xi, t) \in (0, 1) \times (0, T),$$

$$u(0, t) = u(1, t) = 0, \quad t \in [0, T]. \quad (2.5)$$

We recall from elementary theory of partial differential equations that the solution $u(\xi, t)$ of the above heat equation is given by (cf. Weinberger [23])

$$u(\xi, t) = \sum_{n=1}^{\infty} \hat{\varphi}_0(n)e^{-n^2\pi^2t} \sin(n\pi\xi), \quad (2.6)$$

where $\hat{\varphi}_0(n)$ for $n \in \mathbb{N}$ are the Fourier coefficients of the initial temperature $\varphi_0(\xi) := u(\xi, 0)$. Hence,

$$u(\xi, T) = \sum_{n=1}^{\infty} \hat{\varphi}_0(n)e^{-n^2\pi^2T} \sin(n\pi\xi). \quad (2.7)$$
The above equation can be written as
\[
\phi_T(s) = \sum_{n=1}^{\infty} e^{-n^2\pi^2 T} \langle \phi_0, u_n \rangle u_n(\xi) \quad \text{with} \quad u_n(\xi) = \sqrt{2} \sin(n\pi \xi).
\] (2.8)

Thus the problem is to solve the operator equation
\[
A\phi_0 = \phi_T,
\] (2.9)
where \(A : L^2([0,1]) \to L^2([0,1])\) is the operator defined by
\[
(A\phi)(\xi) = \sum_{n=1}^{\infty} e^{-n^2\pi^2 T} \langle \phi, u_n \rangle u_n(\xi) = \int_0^1 k(\xi,t) \phi(t) dt, \quad 0 \leq \xi \leq 1,
\] (2.10)
where
\[
k(\xi,t) := \sum_{n=1}^{\infty} e^{-n^2\pi^2 T} u_n(\xi) u_n(t).
\] (2.11)

Note that the above integral operator is compact, positive, and selfadjoint with positive eigenvalues \(e^{-n^2\pi^2 T}\) and corresponding eigenvectors \(u_n(\cdot)\) for \(n \in \mathbb{N}\).

For considering the regularization of (2.1) in the setting of Hilbert scales, we consider a Hilbert scale \(\{H_t\}_{t \in \mathbb{R}}\) generated by a strictly positive operator \(L : D(L) \to H\) with its domain \(D(L)\) dense in \(H\) satisfying
\[
\|Lx\| \geq \|x\|, \quad x \in D(L).
\] (2.12)

By the operator \(L\) being strictly positive, we mean that \(\langle Lx,x \rangle > 0\) for all nonzero \(x \in H\). Recall (cf. [9]) that the space \(H_t\) is the completion of \(D := \bigcap_{k=0}^{\infty} D(L^k)\) with respect to the norm \(\|x\|_t\), induced by the inner product
\[
\langle u, v \rangle_t = \langle L^t u, L^t v \rangle, \quad u, v \in D.
\] (2.13)

Moreover, if \(\beta \leq \gamma\), then the embedding \(H_\gamma \hookrightarrow H_\beta\) is continuous, and therefore the norm \(\|\cdot\|_\beta\) is also defined in \(H_\gamma\) and there is a constant \(c_{\beta,\gamma}\) such that
\[
\|x\|_\beta \leq c_{\beta,\gamma} \|x\|_\gamma \quad \forall x \in H_\beta.
\] (2.14)

An important inequality that we require in the analysis is the interpolation inequality
\[
\|x\|_\lambda \leq \|x\|_r^\theta \|x\|_t^{1-\theta}, \quad x \in H_t,
\] (2.15)
where
\[
r \leq \lambda \leq t, \quad \theta = \frac{t-\lambda}{t-r},
\] (2.16)
and the moment inequality
\[
\|B^u x\| \leq \|B^v x\|^{u/v} \|x\|^{1-u/v}, \quad 0 \leq u \leq v,
\] (2.17)
where \(B\) is a positive selfadjoint operator (cf. [2]).
We assume that the ill-posed nature of the operator $A$ is related to the Hilbert scale \{${H_t}$\}$_{t \in \mathbb{R}}$ according to the relation

$$c_1 \|x\|_{-a} \leq \|Ax\| \leq c_2 \|x\|_{-a}, \quad x \in H,$$  \hspace{1cm} (2.18)

for some positive reals $a$, $c_1$, and $c_2$.

For the example of the integral operator considered in (2.4), one may take $L$ to be defined by

$$Lx := \sum_{j=1}^{\infty} j^2 \langle x, u_j \rangle u_j,$$  \hspace{1cm} (2.19)

where $u_j(t) := \sqrt{2} \sin(j\pi t)$, $j \in \mathbb{N}$ with domain of $L$ as

$$D(L) := \left\{ x \in L^2[0,1] : \sum_{j=1}^{\infty} j^4 |\langle x, u_j \rangle|^2 < \infty \right\}.$$  \hspace{1cm} (2.20)

In this case, it can be seen that

$$H_t = \left\{ x \in L^2[0,1] : \sum_{j=1}^{\infty} j^{4t} |\langle x, u_j \rangle|^2 < \infty \right\}$$  \hspace{1cm} (2.21)

and the constants $a$, $c_1$, and $c_2$ in (2.18) are given by $a = 1$, $c_1 = c_2 = 1/\pi^2$ (see Schröter and Tautenhahn [20, Section 4]).

The regularized approximation of $\hat{x}$, considered in [4] is the solution of the well-posed equation

$$(A + \alpha L^s)x_\alpha = y, \quad \alpha > 0,$$  \hspace{1cm} (2.22)

where $s$ is a fixed nonnegative real number. Note that if $D(L) = X$ and $L = I$, then the above procedure is the simplified or Lavrentiev regularization.

Suppose the data $y$ is known only approximately, say $\tilde{y}$ in place of $y$ with $\|y - \tilde{y}\| \leq \delta$ for a known error level $\delta > 0$. Then, in place of (2.22), we have

$$(A + \alpha L^s)\hat{x}_\alpha = \tilde{y}.$$  \hspace{1cm} (2.23)

It can be seen that the solution $\hat{x}_\alpha$ of the above equation is the unique minimizer of the function

$$x \mapsto \langle Ax, x \rangle - 2\langle \tilde{y}, x \rangle + \alpha \langle L^s x, x \rangle, \quad x \in D(L).$$  \hspace{1cm} (2.24)

One of the crucial results for proving the results in [4, 5] as well as the results in this paper is the following proposition, where the functions $f$ and $g$ are defined by

$$f(t) = \min \{c_1, c_2^t\}, \quad g(t) = \max \{c_1^t, c_2\}, \quad t \in \mathbb{R}, \quad |t| \leq 1,$$  \hspace{1cm} (2.25)

respectively, with $c_1$, $c_2$ as in (2.18).
**Proposition 2.1** (cf. [4, Proposition 3.1]). For $s > 0$ and $|\nu| \leq 1$,
\[
 f \left( \frac{V}{2} \right) \|x\|_{-\nu(s+a)/2} \leq \|A_s^{\nu/2}x\| \leq g \left( \frac{V}{2} \right) \|x\|_{-\nu(s+a)/2}, \quad x \in H, \tag{2.26}
\]
where $A_s = L^{-s/2}AL^{-s/2}$.

Using the above proposition, the following result has been proved by George and Nair [4].

**Theorem 2.2** (cf. [4, Theorem 3.2]). Suppose $\hat{x} \in H_t$, $0 < t \leq s + a$, and $\alpha > 0$, and $\tilde{x}_\alpha$ is as in (2.23). Then
\[
 \|\hat{x} - \tilde{x}_\alpha\| \leq \phi(s,t)\alpha t/(s+a) \|\hat{x}\|_t + \psi(s)\alpha^{a/(s+a)} \delta, \tag{2.27}
\]
where
\[
 \phi(s,t) = \frac{g((s-2t)/(2s+2a))}{f(s/(2s+2a))}, \quad \psi(s) = \frac{g(-s/(2s+2a))}{f(s/(2s+2a))}. \tag{2.28}
\]

In particular, if $\alpha = c_0\delta^{(s+a)/(t+a)}$ for some constant $c_0 > 0$, then
\[
 \|\hat{x} - \tilde{x}_\alpha\| \leq \eta(s,t)\delta^{t/(t+a)}, \tag{2.29}
\]
where
\[
 \eta(s,t) = \max \left\{ \phi(s,t)\|x\|_tc_0^{t/(t+a)}, \psi(s)c_0^{-a/(s+a)} \right\}. \tag{2.30}
\]

For proposing a finite-dimensional realization, we consider a family $\{S_h : h > 0\}$ of finite-dimensional subspaces of $H_k$ for some $k \geq s$, and consider the minimizer $\tilde{x}_{\alpha,h}$ of the map defined in (2.24) when $x$ varies over $S_h$. Equivalently, $\tilde{x}_{\alpha,h}$ is the unique element in $S_h$ satisfying the equation
\[
 \langle (A + \alpha L^s)\tilde{x}_{\alpha,h}, \varphi \rangle = \langle \hat{y}, \varphi \rangle \quad \forall \varphi \in S_h. \tag{2.31}
\]

As in Engl and Neubauer [3], we assume the following approximation properties for $S_h$. There exists a constant $\kappa > 0$ such that for every $u \in H_r$ with $r > k \geq s$,
\[
 \inf \{ \|u - \varphi\|_k : \varphi \in S_h \} \leq \kappa h^{r-k} \|u\|_r, \quad h > 0. \tag{2.32}
\]

As already exemplified in [3], the above assumption is general enough to include a wide variety of approximations spaces, such as spline spaces and finite element spaces. We will also make use of the following result from Engl and Neubauer [3, Lemma 2.2].

**Lemma 2.3.** Under the assumption (2.32), there exists a constant $c > 0$ such that for every $u \in H_s$ and $h > 0$,
\[
 \inf_{\varphi \in S_h} \left\{ h^{-a/2}\|u - \varphi\|_{-a/2} + h^{s/2}\|u - \varphi\|_{s/2} \right\} \leq ch^s \|u\|_s. \tag{2.33}
\]
3. General error estimates. For a fixed $s > 0$, let $\tilde{x}_\alpha$ and $\tilde{x}_{\alpha,h}$ be as in (2.23) and (2.31), respectively. We will obtain estimate for $\|\tilde{x} - \tilde{x}_{\alpha,h}\|$ so that we get an estimate for $\|\hat{x} - \tilde{x}_{\alpha,h}\|$ using Theorem 2.2 and the relation

$$\|\tilde{x} - \tilde{x}_{\alpha,h}\| \leq \|\hat{x} - \tilde{x}_\alpha\| + \|\tilde{x}_\alpha - \tilde{x}_{\alpha,h}\|. \quad (3.1)$$

In view of the interpolation inequality (2.15), by taking $\rho = -a/2$, $\tau = s/2$, and $\lambda = 0$ in (2.15), we get

$$\|x\| \leq \|x\|_{s/(s-a)}^{a/(s-a)} \|x\|_{s/2}. \quad (3.2)$$

Thus, we can deduce an estimate for $\|\tilde{x}_\alpha - \tilde{x}_{\alpha,h}\|$ once we have estimates for $\|\tilde{x}_\alpha - \tilde{x}_{\alpha,h}\|_{s-a}$ and $\|\tilde{x}_\alpha - \tilde{x}_{\alpha,h}\|_{s/2}$. For this purpose, we first prove the following.

**Lemma 3.1.** Let $\tilde{x}_\alpha$ and $\tilde{x}_{\alpha,h}$ be as in (2.23) and (2.31), respectively. Then

$$\|A^{1/2}(\tilde{x}_\alpha - \tilde{x}_{\alpha,h})\|^2 + \alpha\|\tilde{x}_\alpha - \tilde{x}_{\alpha,h}\|_{s/2}^2 = \inf_{\varphi \in S_h} \{\|A^{1/2}(\tilde{x}_\alpha - \varphi)\|^2 + \alpha\|\tilde{x}_\alpha - \varphi\|_{s/2}^2\}. \quad (3.3)$$

**Proof.** It can be seen (cf. [16]) that

$$\langle u, v \rangle_* := \langle Au, v \rangle + \alpha \langle L^s u, v \rangle, \quad u, v \in D(L), \quad (3.4)$$

defines a complete inner product on $D(L)$. Let $\|\cdot\|_*$ be the norm induced by $\langle \cdot, \cdot \rangle_*$, that is,

$$\|u\|_* = \left(\langle Au, u \rangle + \alpha \langle L^s u, u \rangle\right)^{1/2} = \left(\|A^{1/2} u\|_s^2 + \alpha \|u\|_{s/2}^2\right)^{1/2}. \quad (3.5)$$

Let $X$ be the space $D(L)$ with the inner product $\langle \cdot, \cdot \rangle_*$ and let $P_h$ be the orthogonal projection of $X$ onto the space $S_h$. Then from (2.23) and (2.31) we have

$$\langle (A + \alpha L^s) (\tilde{x}_\alpha - \tilde{x}_{\alpha,h}), \varphi \rangle = 0 \quad \forall \varphi \in S_h, \quad (3.6)$$

that is,

$$\langle \tilde{x}_\alpha - \tilde{x}_{\alpha,h}, \varphi \rangle_* = 0 \quad \forall \varphi \in S_h. \quad (3.7)$$

Hence

$$P_h(\tilde{x}_\alpha - \tilde{x}_{\alpha,h}) = 0 \quad (3.8)$$

so that

$$\|\tilde{x}_\alpha - \tilde{x}_{\alpha,h}\|_* = \inf_{\varphi \in S_h} \| (\tilde{x}_\alpha - \tilde{x}_{\alpha,h}) - \varphi \|_* = \inf_{\varphi \in S_h} \| \tilde{x}_\alpha - \varphi \|_* \quad (3.9)$$

Now the result follows using the definition of $\|\cdot\|_*$. \qed
Next we obtain estimate for \( \| \tilde{x}_\alpha - \tilde{x}_{\alpha,h} \| \) using the estimates for \( \| \tilde{x}_\alpha - \tilde{x}_{\alpha,h} \| - a/2 \) and \( \| \tilde{x}_\alpha - \tilde{x}_{\alpha,h} \| s/2 \). We will use the notation

\[
A_s := L^{-s/2} AL^{-s/2}
\]  

and observe that for \( \alpha > 0 \),

\[
(A + \alpha L) x = L^{s/2} (A_s + \alpha I) L^{s/2} x \quad \forall x \in H_s.
\]  

**Theorem 3.2.** Suppose \( \hat{x} \in H_t \) and assumption (2.32) holds, and let \( \tilde{x}_\alpha \) and \( \tilde{x}_{\alpha,h} \) be as in (2.23) and (2.31), respectively. Then

\[
\| \tilde{x}_\alpha - \tilde{x}_{\alpha,h} \| \leq f \left( \frac{1}{2} \right) \max \left\{ g(s,t,a), h \right\} \Phi(s,h,\alpha)\left( \delta + \alpha \left( t-s \right) / (s+a) \right) h^s,
\]  

where \( f \) and \( g \) are as in (2.25), and

\[
\Phi(s,h,\alpha) = c \max \left\{ g \left( \frac{1}{2} \right) h^{a/2}, \alpha \left( h^{-s/2} \right) \right\}.
\]  

**Proof.** First we prove

\[
\| \tilde{x}_\alpha - \tilde{x}_{\alpha,h} \| - a/2 \leq \frac{1}{f \left( 1/2 \right) \Phi(s,h,\alpha) h^s} \| \tilde{x}_\alpha \| s,
\]  

\[
\| \tilde{x}_\alpha - \tilde{x}_{\alpha,h} \| s/2 \leq \Phi(s,h,\alpha)\alpha^{-1/2} h^s \| \tilde{x}_\alpha \| s,
\]  

\[
\| \tilde{x}_\alpha \| s \leq \Phi(s,a)\alpha^{-1} \delta + g(s,t,a)\alpha \left( t-s \right) / (s+a)
\]  

with \( \Phi(s,a), g(s,t,a) \), and \( \Phi(s,h,\alpha) \) as in the statement of the theorem.

By Lemma 3.1 and Proposition 2.1, it follows that

\[
f \left( \frac{1}{2} \right)^2 \| \tilde{x}_\alpha - \tilde{x}_{\alpha,h} \| - a/2 + \alpha \| \tilde{x}_\alpha - \tilde{x}_{\alpha,h} \| s/2
\]

\[
\leq \inf_{\varphi \in Sh} \left\{ g \left( \frac{1}{2} \right)^2 \| \tilde{x}_\alpha - \varphi \| - a/2 + \alpha \| \tilde{x}_\alpha - \varphi \| s/2 \right\}.
\]  

Note that

\[
g \left( \frac{1}{2} \right)^2 \| \tilde{x}_\alpha - \varphi \| - a/2 + \alpha \| \tilde{x}_\alpha - \varphi \| s/2
\]

\[
\leq \left[ g \left( \frac{1}{2} \right) \| \tilde{x}_\alpha - \varphi \| - a/2 + \alpha^{1/2} \| \tilde{x}_\alpha - \varphi \| s/2 \right]^2.
\]  

\[
\]
But
\[ g \left( \frac{1}{2} \right) ||\tilde{x}_\alpha - \varphi||_{-a/2} + \alpha^{1/2} ||\tilde{x}_\alpha - \varphi||_{s/2} \]
\[ \leq \omega_{h,\alpha,s} \left[ h^{-a/2} ||\tilde{x}_\alpha - \varphi||_{-a/2} + h^{s/2} ||\tilde{x}_\alpha - \varphi||_{s/2} \right], \]
where
\[ \omega(h, \alpha, s) := \max \left\{ g \left( \frac{1}{2} \right) h^{a/2}, \alpha^{1/2} h^{-s/2} \right\}. \]

Hence, by Lemma 2.3, we have
\[ f \left( \frac{1}{2} \right)^2 ||\tilde{x}_\alpha - \tilde{x}_{\alpha,h}||_{-a/2}^2 + \alpha ||\tilde{x}_\alpha - \tilde{x}_{\alpha,h}||_{s/2}^2 \leq \left( \omega(h, \alpha, s) ch^s ||\tilde{x}_\alpha||_s \right)^2. \]

In particular,
\[ f \left( \frac{1}{2} \right)||\tilde{x}_\alpha - \tilde{x}_{\alpha,h}||_{-a/2} \leq \omega(h, \alpha, s) ch^s ||\tilde{x}_\alpha||_s, \]
\[ \alpha^{1/2} ||\tilde{x}_\alpha - \tilde{x}_{\alpha,h}||_{s/2} \leq \omega(h, \alpha, s) ch^s ||\tilde{x}_\alpha||_s. \]

From these, we obtain (3.14) and (3.15).

Now, to prove (3.16), observe from (2.23) and (3.11) that
\[ \tilde{x}_\alpha = L^{-s/2} (A_s + \alpha I)^{-1} L^{-s/2} \tilde{y}. \]

By Proposition 2.1, taking \( \nu = -s/(s + a) \), we have
\[ ||L^{s/2} (A_s + \alpha I)^{-1} L^{-s/2} (\tilde{y} - y)|| \]
\[ \leq \frac{1}{f(-s/(2s + 2a))} \left| \left| A_s^{-s/(2s + 2a)} (A_s + \alpha I)^{-1} L^{-s/2} (\tilde{y} - y) \right| \right| \]
\[ \leq \frac{||((A_s + \alpha I)^{-1}||}{f(-s/(2s + 2a))} \left| \left| A_s^{-s/(2s + 2a)} L^{-s/2} (\tilde{y} - y) \right| \right| \]
\[ \leq \frac{\alpha^{-1} g(-s/(2s + 2a))}{f(-s/(2s + 2a))} ||L^{-s/2} (\tilde{y} - y)||_{s/2} \]
so that
\[ ||L^{s/2} (A_s + \alpha I)^{-1} L^{-s/2} (\tilde{y} - y)|| \leq \tilde{B}(s,a) \alpha^{-1} \delta. \]

Since \( L^{-s/2} y = A_s L^{-s/2} \tilde{x} \), we have
\[ ||L^{s/2} (A_s + \alpha I)^{-1} L^{-s/2} y|| \]
\[ \leq \frac{1}{f(-s/(2s + 2a))} \left| \left| A_s^{-s/(2s + 2a)} (A_s + \alpha I)^{-1} A_s L^{s/2} \tilde{x} \right| \right| \]
\[ \leq \frac{1}{f(-s/(2s + 2a))} \left| \left| (A_s + \alpha I)^{-1} A_s^{((a+1)/(a+s))} \right| \right| \left| \left| A_s^{(s-2t)/(2a+2s)} L^{s/2} \tilde{x} \right| \right|, \]
where
\[ \|A_{s}^{(s-2t)/(2a+2s)} L^{s/2} \hat{x}\| \leq g\left(\frac{s-2t}{2s+2a}\right)\|\hat{x}\|_{t}.\] (3.27)

Since
\[ \|A_{s} + \alpha I\|^{-1} A_{s}^\tau \| \leq \alpha^{-1}, \quad 0 < \tau \leq 1, \] (3.28)
it follows from the above relations that
\[ \|L^{s/2} (A_{s} + \alpha I)^{-1} L^{-s/2} \hat{y}\| \leq g\left(\frac{(s-2t)/(2s+2a)}{f(-s/(2s+2a))}\right)\|\hat{x}\|_{t}\alpha^{(t-s)/(s+a)}.\] (3.29)

Thus, (3.25) and (3.29) give
\[ \|\hat{x}_{\alpha}\|_{s} \leq \|L^{s/2} (A_{s} + \alpha I)^{-1} L^{-s/2} \hat{y}\| \leq \|L^{s/2} (A_{s} + \alpha I)^{-1} L^{s/2} (\hat{y} - y)\| + \|L^{s/2} (A_{s} + \alpha I)^{-1} L^{-s/2} y\| \] (3.30)
\[ \leq F(s,a)\alpha^{-1} \delta + \gamma(s,t,a)\alpha^{(t-s)/(s+a)}. \]

Now, the estimates (3.14) and (3.15) together with the interpolation inequality (3.2) give
\[ \|\hat{x}_{\alpha} - \hat{x}_{\alpha,h}\|_{s} \leq \|\hat{x}_{\alpha} - \hat{x}_{\alpha,h}\|_{s-a/2}^{s/(s+a)} \|\hat{x}_{\alpha} - \hat{x}_{\alpha,h}\|_{s/2}^{s/(s+a)} \leq f\left(\frac{1}{2}\right)^{-s/(s+a)} \alpha^{-a/2(s+a)} \Phi(s,h,\alpha) h^{1/2}\|\hat{x}_{\alpha}\|_{s}.\] (3.31)

From this, the result follows by making use of the estimate (3.16) for \(\hat{x}_{\alpha}\).

\[ \square \]

4. A priori error estimates. Now we choose the regularization parameter \(\alpha\) and discretization parameter \(h\) a priori depending on the noise level \(\delta\) such that optimal order \(O(\delta^{l/(t+a)})\) yields whenever \(\hat{x} \in H_{t}\).

**Theorem 4.1.** Suppose \(\hat{x} \in H_{t}\) with \(0 < t \leq s + a\) and assumption (2.32) holds. Suppose, in addition, that
\[ \alpha = c_{0}\delta^{(s+a)/(t+a)}, \quad h = d_{0}\delta^{1/(t+a)} \] (4.1)
for some constants \(c_{0},d_{0} > 0\). Then, using the notations in Theorems 2.2 and 3.2,
\[ \|\hat{x} - \hat{x}_{\alpha,h}\| \leq [\eta(s,t) + \xi(s,t)]\delta^{l/(t+a)}, \] (4.2)
where

\[\eta(s, t) = \max \left\{ \phi(s, t) \|x\|^{t/(s+a)}, \psi(s) c_0^{-a/(s+a)} \right\},\]

\[\xi(s, t) = c \left[ f \left( \frac{1}{2} \right) \right] ^{-s/(s+a)} \int_0^t \left( c_0^{-1} + c_0^{(t-s)/(t+a)} \right) \times \max \left\{ \mathcal{F}(s, a), \mathcal{G}(s, t, a) \right\} \max \left\{ g \left( \frac{1}{2} \right) d_0^{a/2}, c_0^{-a/2} d_0^{-s/2} \right\}. \]

(4.3)

**Proof.** Using the choice (4.1), it is seen that

\[\Phi(s, h, \alpha) \leq c c_0^{-a/2(s+a)} \max \left\{ g \left( \frac{1}{2} \right) d_0^{a/2}, c_0^{-a/2} d_0^{-s/2} \right\}, \]

\[\delta \alpha^{-1} h^t = c_0^{-1} d_0^s \mathcal{F}^{t/(t+a)}, \]

\[\alpha^{(t-s)/(s+a)} h^s = c_0^{(t-s)/(t+a)} d_0^s \mathcal{G}^{t/(t+a)}. \]

Therefore, by Theorem 3.2, we have

\[\| \hat{x}_\alpha - \hat{x}_{\alpha, h} \| \leq \xi(s, t) \delta^{t/(t+a)} . \]

(4.5)

Also, from Theorem 2.2, we have

\[\| \hat{x} - \hat{x}_\alpha \| \leq \eta(s, t) \delta^{t/(t+a)} . \]

(4.6)

Thus the result follows from the inequality

\[\| \hat{x} - \hat{x}_\alpha \| \leq \| \hat{x} - \hat{x}_\alpha \| + \| \hat{x}_\alpha - \hat{x}_{\alpha, h} \|. \]

(4.7)

**Remark 4.2.** We observe that the error bound obtained is of the same order as of Theorem 2.2, and this order is optimal with respect to the source set

\[M_{I, t} = \{ x \in H_t : \|x\|_t \leq \rho \}. \]

(4.8)

in the sense of the best possible worst error (cf. [4]).

5. Discrepancy principle. In this section, we consider a discrepancy principle to choose the regularization parameter \( \alpha \) depending on the noise level \( \delta \) and the discretization parameter \( h \). This is a finite-dimensional variant of the discrepancy principle considered in [5].
We assume throughout that $y \neq 0$. Suppose that $\tilde{y} \in H$ is such that
\[
\|y - \tilde{y}\| \leq \delta
\] (5.1)
for a known error level $\delta > 0$ and $P_h \tilde{y} \neq 0$, where $P_h$ is the orthogonal projection of $H$ onto $S_h$. We assume, throughout this section, that
\[
\|A(P_h - I)\| \leq c_3 h, \quad h > 0,
\] (5.2)
for some $c_3 > 0$, independent of $h$. Let
\[
R_\alpha := (A_s + \alpha I)^{-1}.
\] (5.3)

We will make use of the relation
\[
\|R_\alpha A^\tau\| \leq \alpha^{\tau-1}, \quad \alpha > 0, \quad 0 < \tau \leq 1,
\] (5.4)
which follows from the spectral properties of the selfadjoint operator $A_s, s > 0$.

Let $s, a$ be fixed positive real numbers. For $\alpha > 0$ and $x \in H$, consider the functions
\[
F(\alpha, x) = \alpha \frac{\|R_\alpha^{3/2} A_s^{-s/(2s+2a)} L^{-s/2} P_h x\|^2}{\|R_\alpha^{5/2} A_s^{-s/(2s+2a)} L^{-s/2} P_h x\|^2}.
\] (5.5)

Note that, by assumption (2.18), $\|R_\alpha^{5/2} A_s^{-s/(2s+2a)} L^{-s/2} P_h x\|$ is nonzero for every $x \in H$ with $P_h x \neq 0$, so that the function $F(\alpha, x)$ is well defined for all such $x$. We observe that the assumption $P_h x \neq 0$ is satisfied for $x \neq 0$ and $h$ small enough, if $P_h x \to x$ as $h \to 0$ for every $x \in H$.

In the following, we assume that $h$ is such that $P_h \tilde{y} \neq 0$.

In order to choose the regularization parameter $\alpha$, we consider the discrepancy principle
\[
F(\alpha, \tilde{y}) = b \delta + dh
\] (5.6)
for some $b, d > 0$. In the due course, we will make use of the relation
\[
f \left( \frac{-s}{2s+2a} \right) \|x\| \leq \|A_s^{-s/(2s+2a)} L^{-s/2} x\| \leq \theta \left( \frac{-s}{2s+2a} \right) \|x\|
\] (5.7)
which can easily be derived from Proposition 2.1.

First we prove the monotonicity of the function $F(\alpha, x)$ defined in (5.5).
Similarly, we obtain

\[
\frac{\partial}{\partial \alpha} F(\alpha, x) = \frac{(\partial/\partial \alpha)(F^2(\alpha, x))}{2F(\alpha, x)}
\]

\[
= 2\alpha \left| R^2_{\alpha} A^{-s/(2s+2a)} L^{-s/2} P_h x \right|^2 \left| R^{3/2}_{\alpha} A^{-s/(2s+2a)} L^{-s/2} P_h x \right|^2 \\
\leq \frac{2\alpha \left| R^{3/2}_{\alpha} A^{-s/(2s+2a)} L^{-s/2} P_h x \right|^2}{2\alpha \left| R^{3/2}_{\alpha} A^{-s/(2s+2a)} L^{-s/2} P_h x \right|^2}
\]

\[
\times \left[ (\partial/\partial \alpha) \left[ \left| R^{3/2}_{\alpha} A^{-s/(2s+2a)} L^{-s/2} P_h x \right|^2 \right] \right]
\]

\[
- \frac{\alpha^2 \left| R^{3/2}_{\alpha} A^{-s/(2s+2a)} L^{-s/2} P_h x \right|^4}{2\alpha \left| R^{3/2}_{\alpha} A^{-s/(2s+2a)} L^{-s/2} P_h x \right|^2 \left| R^{3/2}_{\alpha} A^{-s/(2s+2a)} L^{-s/2} P_h x \right|^2}
\]

\[
= \frac{\left| R^{3/2}_{\alpha} A^{-s/(2s+2a)} L^{-s/2} P_h x \right|^2}{2\left| R^{3/2}_{\alpha} A^{-s/(2s+2a)} L^{-s/2} P_h x \right|^2 \left| R^{3/2}_{\alpha} A^{-s/(2s+2a)} L^{-s/2} P_h x \right|^2}
\]

Let \(E_{\lambda} : 0 \leq \lambda \leq a\) be the spectral family of \(A_s\), where \(a \geq \|A_s\|\). Then

\[
\frac{\partial}{\partial \alpha} \left( \alpha \left| R^{3/2}_{\alpha} A^{-s/(2s+2a)} L^{-s/2} P_h x \right|^2 \right)
\]

\[
= \frac{\partial}{\partial \alpha} \left[ \int_0^{\alpha} \frac{\alpha}{\lambda^{s/(s+a)}} (\lambda + \alpha)^3 d \langle E_{\lambda} L^{-s/2} P_h x, L^{-s/2} P_h x \rangle \right]
\]

\[
= \int_0^{\lambda^2} \left[ \frac{1}{\lambda^{s/(s+a)}} (\lambda + \alpha)^3 - \frac{3\alpha}{\lambda^{s/(s+a)}} (\lambda + \alpha)^4 \right] d \langle E_{\lambda} L^{-s/2} P_h x, L^{-s/2} P_h x \rangle
\]

\[
= \left| R^{3/2}_{\alpha} A^{-s/(2s+2a)} L^{-s/2} P_h x \right|^2 - 3\alpha \left| R^{3/2}_{\alpha} A^{-s/(2s+2a)} L^{-s/2} P_h x \right|^2
\]

Similarly, we obtain

\[
\frac{\partial}{\partial \alpha} \left( \left| R^{3/2}_{\alpha} A^{-s/(2s+2a)} L^{-s/2} P_h x \right| \right) = -4\left| R^{5/2}_{\alpha} A^{-s/(2s+2a)} L^{-s/2} P_h x \right|^2.
\]
Therefore, from (5.9), by using (5.10) and (5.11), we get

\[
\frac{\partial}{\partial \alpha} F(\alpha, x) = \frac{||R_{\alpha}^{2}A_{s}^{-s/(2s+2a)}L^{-s/2}P_{h}x||^{2}}{||R_{\alpha}^{2}A_{s}^{-s/(2s+2a)}L^{-s/2}P_{h}x||^{3}} \\
\times \left[ ||R_{\alpha}^{3/2}A_{s}^{-s/(2s+2a)}L^{-s/2}P_{h}x||^{2} - 3\alpha||R_{\alpha}^{2}A_{s}^{-s/(2s+2a)}L^{-s/2}P_{h}x||^{2} \right]^{2} \\
+ \frac{2\alpha||R_{\alpha}^{3/2}A_{s}^{-s/(2s+2a)}L^{-s/2}P_{h}x||^{2}||R_{\alpha}^{5/2}A_{s}^{-s/(2s+2a)}L^{-s/2}P_{h}x||^{2}}{||R_{\alpha}^{2}A_{s}^{-s/(2s+2a)}L^{-s/2}P_{h}x||^{3}}. 
\] (5.12)

The above equation can be rewritten as

\[
\frac{\partial}{\partial \alpha} F(\alpha, x) = \frac{||R_{\alpha}^{2}A_{s}^{-s/(2s+2a)}L^{-s/2}P_{h}x||^{2}}{||R_{\alpha}^{2}A_{s}^{-s/(2s+2a)}L^{-s/2}P_{h}x||^{3}} \\
\times \left[ ||R_{\alpha}^{3/2}A_{s}^{-s/(2s+2a)}L^{-s/2}P_{h}x||^{2} - \alpha||R_{\alpha}^{2}A_{s}^{-s/(2s+2a)}L^{-s/2}P_{h}x||^{2} \right]^{2} \\
+ \frac{2\alpha}{||R_{\alpha}^{2}A_{s}^{-s/(2s+2a)}L^{-s/2}P_{h}x||^{3}} \\
\times \left[ ||R_{\alpha}^{3/2}A_{s}^{-s/(2s+2a)}L^{-s/2}P_{h}x||^{2}||R_{\alpha}^{5/2}A_{s}^{-s/(2s+2a)}L^{-s/2}P_{h}x||^{2} \right. \\
\left. - ||R_{\alpha}^{2}A_{s}^{-s/(2s+2a)}L^{-s/2}P_{h}x||^{4} \right]. 
\] (5.13)

Since

\[
||R_{\alpha}^{3/2}A_{s}^{-s/(2s+2a)}L^{-s/2}P_{h}x||^{2} = \langle (A_{s} + \alpha I)^{-3}A_{s}^{-s/(2s+2a)}L^{-s/2}P_{h}x, A_{s}^{-s/(2s+2a)}L^{-s/2}P_{h}x \rangle, 
\] (5.14)

we see that

\[
||R_{\alpha}^{3/2}A_{s}^{-s/(2s+2a)}L^{-s/2}P_{h}x||^{2} = \alpha||R_{\alpha}^{2}A_{s}^{-s/(2s+2a)}L^{-s/2}P_{h}x||^{2} \\
+ \langle (A_{s} + \alpha I)^{-3}A_{s}^{-s/(2s+2a)}L^{-s/2}P_{h}x, A_{s} + \alpha I \rangle^{-1}A_{s}^{-s/(2s+2a)}L^{-s/2}P_{h}x \rangle \rangle^{-1}A_{s}^{-s/(2s+2a)}L^{-s/2}P_{h}x, 
\] (5.15)
Also, we have
\[
\|R_2^s A_{s}^{-s/(2s+2a)} L^{-s/2} P_h x\|^4
= \left( \langle R_2^s A_{s}^{-s/(2s+2a)} L^{-s/2} P_h x, R_2^s A_{s}^{-s/(2s+2a)} L^{-s/2} P_h x \rangle \right)^2
\]
\[
= \left( \langle R_2^s A_{s}^{-s/(2s+2a)} L^{-s/2} P_h x, R_2^s A_{s}^{-s/(2s+2a)} L^{-s/2} P_h x \rangle \right)^2
\]
\[
\leq \|R_2^s A_{s}^{-s/(2s+2a)} L^{-s/2} P_h x\|^2 \cdot \|R_3^s A_{s}^{-s/(2s+2a)} L^{-s/2} P_h x\|^2.
\]

Hence,
\[
\frac{\partial}{\partial \alpha} (F(\alpha, x)) \geq 0.
\]

To prove the last part of the theorem, we observe that
\[
\alpha^2 \|R_2^s A_{s}^{-s/(2s+2a)} L^{-s/2} P_h x\| - F(\alpha, x)
= \alpha^2 \|R_2^s A_{s}^{-s/(2s+2a)} L^{-s/2} P_h x\|^2 - \alpha \|R_3^s A_{s}^{-s/(2s+2a)} L^{-s/2} P_h x\|^2
\]
\[
= \frac{\alpha^2 \|R_2^s A_{s}^{-s/(2s+2a)} L^{-s/2} P_h x\|^2 - \alpha \|R_3^s A_{s}^{-s/(2s+2a)} L^{-s/2} P_h x\|^2}{\|R_2^s A_{s}^{-s/(2s+2a)} L^{-s/2} P_h x\|}.
\]

We note that
\[
\alpha^2 \|R_2^s A_{s}^{-s/(2s+2a)} L^{-s/2} P_h x\|^2 = \alpha \langle R_3^s A_{s}^{-s/(2s+2a)} L^{-s/2} P_h x, \alpha R_2^s A_{s}^{-s/(2s+2a)} L^{-s/2} P_h x \rangle,
\]
\[
\alpha \|R_3^s A_{s}^{-s/(2s+2a)} L^{-s/2} P_h x\|^2 = \alpha \langle R_3^s A_{s}^{-s/(2s+2a)} L^{-s/2} P_h x, A_{s}^{-s/(2s+2a)} L^{-s/2} P_h x \rangle.
\]

Since
\[
\alpha R_\alpha - I = A_\alpha R_\alpha = R_\alpha A_\alpha,
\]
it follows that
\[
\alpha^2 \|R_2^s A_{s}^{-s/(2s+2a)} L^{-s/2} P_h x\| - F(\alpha, x)
= -\alpha \langle R_3^s A_{s}^{-s/(2s+2a)} L^{-s/2} P_h x, A_\alpha A_{s}^{-s/(2s+2a)} L^{-s/2} P_h x \rangle
\]
\[
= -\alpha \|A_{s}^{-s/(2s+2a)} R_3^s L^{-s/2} P_h x\|^2
\]
\[
= -\alpha \|R_3^s A_{s}^{-s/(2s+2a)} L^{-s/2} P_h x\|^2
\]
\[
\leq 0
\]
so that
\[
F(\alpha, x) \geq \alpha^2 \|R_2^s A_{s}^{-s/(2s+2a)} L^{-s/2} P_h x\| \geq \alpha^2 \|A_{s}^{-s/(2s+2a)} L^{-s/2} P_h x\|^2
= \alpha^2 \left( \|A_{s}\| + \alpha \right)^2.
\]
Also, we have
\[
F(\alpha, x) = \frac{\alpha (R_\alpha A_{s}^{-s/(2s+2a)} L^{-s/2} P_h x, R_\alpha^2 A_{s}^{-s/(2s+2a)} L^{-s/2} P_h x)}{\|R_\alpha A_{s}^{-s/(2s+2a)} L^{-s/2} P_h x\|}
\]
\[
\leq \alpha \|R_\alpha A_{s}^{-s/(2s+2a)} L^{-s/2} P_h x\|. \tag{5.23}
\]
Hence
\[
\left(\frac{\alpha}{\|A_s\| + \alpha}\right)^2 \|A_{s}^{-s/(2s+2a)} L^{-s/2} P_h x\| \leq F(\alpha, x) \leq \alpha \|A_{s}^{-s/(2s+2a)} L^{-s/2} P_h x\|. \tag{5.24}
\]
From this we can conclude that
\[
\lim_{\alpha \to 0} F(\alpha, x) = 0, \quad \lim_{\alpha \to \infty} F(\alpha, x) = \|A_{s}^{-s/(2s+2a)} L^{-s/2} P_h x\|. \tag{5.25}
\]
This completes the proof. \qed

For the next theorem, in addition to (5.1), we assume that the inexact data \(\tilde{y}\) satisfies the relation
\[
\|A_{s}^{-s/(2s+2a)} L^{-s/2} P_h \tilde{y}\| \geq b\delta + dh. \tag{5.26}
\]
This assumption is satisfied for small enough \(h\) and \(\delta\), if, for example,
\[
(b + \hat{f}(s))\delta + (d + c_3 \hat{f}(s) \|\hat{x}\|)h \leq \hat{f}(s) \|y\|, \tag{5.27}
\]
where \(\hat{f}(s) = f(-s/(2s+2a))\), because
\[
\|P_h \tilde{y}\| \geq \|y\| - \|(I - P_h) A\hat{x}\| - \delta, \tag{5.28}
\]
and by (5.7),
\[
\|A_{s}^{-s/(2s+2a)} L^{-s/2} P_h \tilde{y}\| \leq \hat{f}(s) \|P_h \tilde{y}\|. \tag{5.29}
\]
Now the following theorem is a consequence of Theorem 5.1.

**Theorem 5.2.** Assume that (5.1) and (5.26) are satisfied. Then there exists a unique \(\alpha := \alpha(\delta, h)\) satisfying
\[
F(\alpha, \tilde{y}) = b\delta + dh. \tag{5.30}
\]

In order to obtain an estimate for the error \(\|\hat{x} - \hat{x}_\alpha\|\) with the parameter choice strategy (5.30), we will make use of (3.31). The next lemma gives an error estimate for \(\|\hat{x}_\alpha\|_s\) in terms of \(\alpha = \alpha(\delta, h)\), \(\delta\), and \(h\).

**Lemma 5.3.** Let \(\alpha := \alpha(\delta, h)\) be the unique solution of (5.30). Then for any fixed \(\tau > 0\),
\[
\|\hat{x}_\alpha\|_s \leq c_4 (\delta + h)^{\tau/(\tau+1)} \alpha^{-1}, \tag{5.31}
\]
where
\[ c_4 = \max \{ b + \tilde{g}(s), c + c_3 \| \tilde{x} \| \tilde{g}(s) \| \tilde{y} \| \} \] (5.32)

with \( \tilde{g}(s) := g(-s/(2s + 2a)) \).

**Proof.** By (3.30), we have
\[ \| \tilde{x}(t) \| \leq \| L_{s/2} R_{\alpha} L^{-s/2} \tilde{y}(t) \| \leq \tilde{f}^{-1}(s) \alpha^{-1} \| \alpha R_{\alpha} A_s^{-s/(2s + 2a)} L^{-s/2} \tilde{y}(t) \|. \] (5.33)

To obtain an estimate for \( \| \alpha R_{\alpha} A_s^{-s/(2s + 2a)} L^{-s/2} \tilde{y}(t) \| \), we will make use of the moment inequality (2.17). Precisely, we use (2.17) with
\[ u = \tau, \quad v = 1 + \tau, \quad B = \alpha R_{\alpha}, \quad x = \alpha^{1-\tau} R_{\alpha}^{1-\tau} A_s^{-s/(2s + 2a)} L^{-s/2} \tilde{y}(t). \] (5.34)

Then, since
\[ \| x \| \leq \| A_s^{-s/(2s + 2a)} L^{-s/2} \tilde{y}(t) \| \leq \tilde{g} \left( \frac{s}{2s + 2a} \right) \| \tilde{y}(t) \|, \] (5.35)

we have
\[ \| \alpha R_{\alpha} A_s^{-s/(2s + 2a)} L^{-s/2} \tilde{y}(t) \| \]
\[ = \| B^T x \| \leq \| B^{T+1} x \| / \| x \| \]
\[ = \| \alpha^2 R_{\alpha}^2 A_s^{-s/(2s + 2a)} L^{-s/2} \tilde{y}(t) \| / \| x \| \]
\[ = \| \alpha^2 R_{\alpha}^2 A_s^{-s/(2s + 2a)} L^{-s/2} \tilde{y}(t) \| / \| x \| \]
\[ = \tilde{g}(s) \| (I - P_h) \tilde{y}(t) \| + F(\alpha, \tilde{y}) \] (5.36)
\[ \leq \tilde{g}(s) \| (I - P_h) (\tilde{y} - \gamma) \| + \| (I - P_h) A \tilde{x} \| + F(\alpha, \tilde{y}) \]
\[ \leq \tilde{g}(s) [\delta + c_3 \| \tilde{x} \|] + F(\alpha, \tilde{y}). \]

Further, by (5.21),
\[ \| \alpha^2 R_{\alpha}^2 A_s^{-s/(2s + 2a)} L^{-s/2} \tilde{y}(t) \|
\[ \leq \| \alpha^2 R_{\alpha}^2 A_s^{-s/(2s + 2a)} L^{-s/2} (I - P_h) \tilde{y}(t) \| + \| \alpha^2 R_{\alpha}^2 A_s^{-s/(2s + 2a)} L^{-s/2} P_h \tilde{y}(t) \|
\[ \leq \tilde{g}(s) \| (I - P_h) \tilde{y}(t) \| + F(\alpha, \tilde{y}) \] (5.37)
\[ \leq \tilde{g}(s) [\delta + c_3 \| \tilde{x} \|] + F(\alpha, \tilde{y}). \]

Therefore, if \( \alpha := \alpha(\delta, h) \) is the unique solution of (5.30), then we have
\[ \| \alpha^2 R_{\alpha}^2 A_s^{-s/(2s + 2a)} L^{-s/2} \tilde{y}(t) \| \leq (b + \tilde{g}(s)) \delta + (d + \tilde{g}(s)c_3 \| \tilde{x} \|) h. \] (5.38)

Now the result follows from (5.33), (5.36), (5.37), and (5.38).

**Lemma 5.4.** Suppose that \( \tilde{x} \) belongs to \( H_t \) for some \( t \leq s \), and \( \alpha := \alpha(\delta, h) > 0 \) is the unique solution of (5.30), where \( b > \tilde{g}(s) \) and \( d > c_3 \| \tilde{x} \| \tilde{g}(s) \) with \( \tilde{g}(s) := g(-s/(2s + 2a)) \). Then
\[ \alpha \geq c_0 \delta^{(s+a)/(t+a)}, \quad c_0 = \frac{\min \{ b - \tilde{g}(s), d - c_3 \| \tilde{x} \| \tilde{g}(s) \}}{g((s-2t)/(2s + 2a)) \rho}. \] (5.39)
Proof. Note that by (5.23), Proposition 2.1, and (2.18), we have

\[
F(\alpha, \tilde{y}) \leq \alpha \| R_\alpha A_s^{-s/(2s+2a)} L^{-s/2} P_h \tilde{y} \|
\]

\[
\leq \alpha \| R_\alpha A_s^{-s/(2s+2a)} L^{-s/2} P_h (\tilde{y} - y) \|
\]

\[
+ \alpha \| R_\alpha A_s^{-s/(2s+2a)} L^{-s/2} (P_h - I) y \|
\]

\[
+ \alpha \| R_\alpha A_s^{-s/(2s+2a)} A_s L^{s/2} \hat{x} \|
\]

\[
\leq \alpha \| R_\alpha A_s^{-s/(2s+2a)} L^{-s/2} P_h (\tilde{y} - y) \|
\]

\[
+ \alpha \| R_\alpha A_s^{-s/(2s+2a)} L^{-s/2} (P_h - I) y \|
\]

\[
+ \alpha \| R_\alpha A_s^{(s+2a)/(2s+2a)} L^{s/2} \hat{x} \|
\]

\[
\leq \tilde{g}(s) \left[ \delta + c_3 \| \hat{x} \| \right] + \| \alpha R_\alpha A_s^{(t+a)/(s+a)} \| \| A_s^{(s-2t)/(2s+2a)} L^{s/2} \hat{x} \|
\]

\[
\leq \tilde{g}(s) \left[ \delta + c_3 \| \hat{x} \| \right] + g \left( \frac{s-2t}{2s+2a} \right) \rho \alpha^{(t+a)/(s+a)}. \tag{5.40}
\]

Thus

\[
\min \{ b - \tilde{g}(s), d - c_3 \| \hat{x} \| \| \tilde{g}(s) \| (\delta + h) \leq g \left( \frac{s-2t}{2s+2a} \right) \rho \alpha^{(t+a)/(s+a)}, \tag{5.41}
\]

which implies

\[
\alpha \geq c_0 (\delta + h)^{(s+a)/(t+a)}, \quad c_0 = \min \left\{ \frac{b - \tilde{g}(s), d - c_3 \| \hat{x} \| \| \tilde{g}(s) \|}{g((s-2t)/(2s+2a)) \rho} \right\}. \tag{5.42}
\]

This completes the proof. \qed

**Theorem 5.5.** Under the assumptions in Lemma 5.4, for any fixed \( \tau > 0 \),

\[
\| \hat{x}_\alpha - \tilde{x}_{\alpha,h} \| \leq c_5 (\delta + h) \zeta, \tag{5.43}
\]

where

\[
\zeta := \frac{\tau}{\tau + 1} + \frac{s}{2} \frac{s + 2a}{2t + 2a} + \gamma, \quad c_5 \geq cc_4 f \left( \frac{1}{2} \right)^{-s/(s+a)} \max \left\{ g \left( \frac{1}{2} \right), 1 \right\} \tag{5.44}
\]

with

\[
\gamma := \begin{cases} 0, & \text{if } t \geq 1 - a, \\ \frac{s + a}{2} \left( 1 - \frac{1}{t + a} \right), & \text{if } t < 1 - a. \end{cases} \tag{5.45}
\]
PROOF. Note that by (3.31) and Lemmas 5.3 and 5.4,

\[ ||\hat{x}_\alpha - \tilde{x}_{\alpha,h}|| \leq f\left(\frac{1}{2}\right)^{-s/(s+a)} \Phi(s,h,\alpha) \alpha^{-a/(2s+2a)} h^s ||\tilde{x}_\alpha||_s \]

\[ \leq c f\left(\frac{1}{2}\right)^{-s/(s+a)} \max \left\{ \mathcal{g}\left(\frac{1}{2}\right) h^{a/2}, \alpha^{1/2} h^{-s/2} \right\} c_4 \alpha^{-a/(2s+2a)} h^s \alpha^{-1}(\delta + h)^{\tau/((\tau+1))} \]

\[ \leq c f\left(\frac{1}{2}\right)^{-s/(s+a)} \max \left\{ \mathcal{g}\left(\frac{1}{2}\right) h^{(s+a)/2} \alpha^{-1/2}, 1 \right\} c_4 \alpha^{-a/(2s+2a)} - 1/2 h^{s/2} (\delta + h)^{\tau/((\tau+1))} \]

\[ \times c_4 (\delta + h)^{\tau/((\tau+1)+s/2-a/(2t+2a)-(s+a)/(2t+2a)} \]

\[ \leq c f\left(\frac{1}{2}\right)^{-s/(s+a)} \max \left\{ \mathcal{g}\left(\frac{1}{2}\right), 1 \right\} c_4 (\delta + h)^{\tau/((\tau+1)+s/2-a/(2t+2a)-(s+a)/(2t+2a)+\gamma} \]

\[ \leq c f\left(\frac{1}{2}\right)^{-s/(s+a)} \max \left\{ \mathcal{g}\left(\frac{1}{2}\right), 1 \right\} c_4 (\delta + h)^{\tau/((\tau+1)+s/2-a/(2t+2a)-(s+a)/(2t+2a)+\gamma} \]

\[ \leq c f\left(\frac{1}{2}\right)^{-s/(s+a)} \max \left\{ \mathcal{g}\left(\frac{1}{2}\right), 1 \right\} c_4 (\delta + h)^{\tau/((\tau+1)+s/2-a/(2t+2a)-(s+a)/(2t+2a)+\gamma} \]

This completes the proof.

\[ (5.46) \]

**Theorem 5.6.** Under the assumptions in Lemma 5.4,

\[ ||\hat{x} - x_\alpha|| = O((\delta + h)^{t/(t+a)}). \]

\[ (5.47) \]

**Proof.** Since \( x_\alpha \) is the solution of (2.22), we have

\[ \hat{x} - x_\alpha = \hat{x} - (A + \alpha L^s)^{-1} \gamma \]

\[ = \alpha L^{-s/2} (A_\delta + \alpha I)^{-1} L^{s/2} \hat{x} \]

\[ = \alpha L^{-s/2} R_\alpha L^{s/2} \hat{x}. \]

\[ (5.48) \]

Therefore, by (5.7), we have

\[ f\left(\frac{s}{2s+2a}\right)||\hat{x} - x_\alpha|| \leq ||\alpha A_s^{s/(2s+2a)} R_\alpha L^{s/2} \hat{x}||. \]

\[ (5.49) \]

To obtain an estimate for \( ||\alpha A_s^{s/(2s+2a)} R_\alpha L^{s/2} \hat{x}|| \), first we will make use the moment inequality (2.17) with

\[ u = \frac{t}{a}, \quad v = 1 + \frac{t}{a}, \quad B = \alpha R_\alpha A_{\delta}^{s/(s+a)}, \quad x = \alpha^{1-t/a} R_\alpha A_{\delta}^{s-2t/(2s+2a)} L^{s/2} \hat{x}. \]

\[ (5.50) \]
Then, since
\[\|x\| \leq \left\| A_s^{(s-2t)/(2s+2a)} L^{s/2} \hat{x} \right\| \leq g \left( \frac{s-2t}{2s+2a} \right) \left\| L^{s/2} \hat{x} \right\|_{s/2} \leq g \left( \frac{s-2t}{2s+2a} \right) \rho, \quad (5.51)\]
we have
\[
\left\| \alpha A_s^{s/(2s+2a)} R^L_{\alpha} L^{s/2} \hat{x} \right\|
= \left\| B^{t/a} x \right\|
\leq \left\| B^{1+t/a} x \right\|^{t/(t+a)} \left\| x \right\|^{a/(t+a)}
\leq \left\| \alpha^2 R^2_{\alpha} A_s^{(2a+s)/(2s+2a)} L^{s/2} \hat{x} \right\|^{t/(t+a)} \left\| x \right\|^{a/(t+a)}
\leq \left\| \alpha^2 R^2_{\alpha} A_s^{-s/(2s+2a)} L^{-s/2} \hat{y} \right\|^{t/(t+a)} \left\| x \right\|^{a/(t+a)}
\leq g \left( \frac{s-2t}{2s+2a} \right)^{a/(t+a)} \rho^{a/(t+a)} \left\| \alpha^2 R^2_{\alpha} A_s^{-s/(2s+2a)} L^{-s/2} \hat{y} \right\|^{t/(t+a)}. \quad (5.52)
\]
Further, by (5.2), (5.7), and (5.21),
\[
\left\| \alpha^2 R^2_{\alpha} A_s^{-s/(2s+2a)} L^{-s/2} \hat{y} \right\|
\leq \left\| \alpha^2 R^2_{\alpha} A_s^{-s/(2s+2a)} L^{-s/2} (Y - \hat{y}) \right\| + \left\| \alpha^2 R^2_{\alpha} A_s^{-s/(2s+2a)} L^{-s/2} (I - P_h) \hat{y} \right\|
+ \left\| \alpha^2 R^2_{\alpha} A_s^{-s/(2s+2a)} L^{-s/2} P_h \hat{y} \right\|
\leq g \left( -\frac{s}{2s+2a} \right) (\delta + c_3 \left\| \hat{x} \right\| h) + F(\alpha, \hat{y}). \quad (5.53)
\]
Therefore, if \( \alpha := \alpha(\delta, h) \) is the unique solution of (5.30), then we have
\[
\left\| \alpha^2 R^2_{\alpha} A_s^{-s/(2s+2a)} L^{-s/2} \hat{y} \right\| \leq \left[ \hat{g}(s) + b \right] \delta + \left[ \hat{g}(s) c_3 \left\| \hat{x} \right\| + d \right] h. \quad (5.54)
\]
Now the result follows from (5.49), (5.52), (5.53), and (5.54).

**Theorem 5.7.** Under the assumptions in Lemma 5.4, for any fixed \( \tau > 0 \),
\[
\left\| \hat{x} - \hat{x}_{\alpha,h} \right\| \leq c_6 (\delta + h)^{\mu}, \quad \mu := \min \left\{ \frac{t}{t+a}, \zeta \right\} \quad (5.55)
\]
for some \( c_6 > 0 \), and \( \zeta \) as in Theorem 5.5.
PROOF. Let $x_{\alpha}$ and $\hat{x}_{\alpha}$ be the solutions of (2.22) and (2.23), respectively. Then by triangle inequality, (5.4), and Proposition 2.1,

$$
||\hat{x} - \hat{x}_{\alpha,h}|| \\
\leq ||\hat{x} - x_{\alpha}|| + ||x_{\alpha} - \hat{x}_{\alpha}|| + ||\hat{x}_{\alpha} - \hat{x}_{\alpha,h}|| \\
= ||\hat{x} - x_{\alpha}|| + ||L^{-s/2}R_{\alpha}L^{-s/2}(y - \tilde{y})|| + ||\hat{x}_{\alpha} - \hat{x}_{\alpha,h}|| \\
\leq ||\hat{x} - x_{\alpha}|| + \frac{1}{f(s/(2s + 2a))} ||A_s^{s/(2s + 2a)}R_{\alpha}L^{-s/2}(y - \tilde{y})|| + ||\hat{x}_{\alpha} - \hat{x}_{\alpha,h}|| \\
\leq ||\hat{x} - x_{\alpha}|| + \frac{1}{f(s/(2s + 2a))} ||A_s^{s/(s+a)}R_{\alpha}A_s^{-s/(2s + 2a)}L^{-s/2}(y - \tilde{y})|| + ||\hat{x}_{\alpha} - \hat{x}_{\alpha,h}|| \\
\leq ||\hat{x} - x_{\alpha}|| + g\left(-s/(2s + 2a)\right)\delta^{a/(s+a)} + ||\hat{x}_{\alpha} - \hat{x}_{\alpha,h}|| \\
\leq ||\hat{x} - x_{\alpha}|| + g\left(-s/(2s + 2a)\right)\delta^{a/(s+a)} + ||\hat{x}_{\alpha} - \hat{x}_{\alpha,h}||.
$$

(5.56)

The proof now follows from Lemma 5.4 and Theorems 5.5 and 5.6. 

COROLLARY 5.8. If $t, s, a$ satisfy $\max\{0, 1 - a\} < t \leq s$ and $\tau$ is large enough such that

$$
\gamma + \frac{s}{2} \left[1 - \frac{1}{t + a}\right] \geq \frac{1}{\tau + 1},
$$

(5.57)

then

$$
||\hat{x} - \hat{x}_{\alpha,h}|| \leq c_6(\delta + h)^{t/(t+a)}
$$

(5.58)

with $c_6$ as in Theorem 5.7.

PROOF. Let $\zeta$, $\mu$ be as in Theorems 5.5 and 5.7, respectively. Then we observe that

$$
\mu = \frac{t}{t + a} \quad \text{if} \quad \gamma + \frac{s}{2} \left[1 - \frac{1}{t + a}\right] \geq \frac{1}{\tau + 1}.
$$

(5.59)

Hence the result follows from Theorem 5.7. 

6. Order optimality of the error estimates. In order to measure the quality of an algorithm to solve an equation of the form (2.1), Micchelli and Rivlin [12] considered the quantity

$$
e(M, \delta) := \sup \{||x|| : x \in M, ||Ax|| \leq \delta\}
$$

(6.1)

and showed that

$$
e(M, \delta) \leq E(M, \delta) \leq 2e(M, \delta),
$$

(6.2)
where
\[ E(M, \delta) = \inf_R \sup_x \{ \|x - Rv\| : x \in M, v \in H, \|Ax - v\| \leq \delta \} \]  
(6.3)
is the best possible worst error. Here the stabilizing set \( M \) is assumed to be convex such that \( M = -M \) with \( 0 \in M \) (see also, Vainikko and Veretennikov [22]), and infimum is taken over all algorithms \( R : Y \to X \). Since \( H \) is a Hilbert space and \( A \) is assumed to be selfadjoint and positive, we, in fact, have (cf. Melkman and Micchelli [11])
\[ e(M, \delta) = E(M, \delta). \]  
(6.4)

Now using the assumption (2.18), and taking \( r = -a, \lambda = 0 \) in the interpolation inequality (2.15), we obtain
\[ \|x\| \leq \|x\|^{t/(t+a)} \|x\|^{a/(t+a)} \leq \left( \frac{\|Ax\|}{c_1} \right)^{t/(t+a)} \|x\|^{a/(t+a)}, \ x \in H_t. \]  
(6.5)

Therefore, for the set
\[ M_{t, \rho} = \{x : \|x\|_t \leq \rho\} \]  
(6.6)
with a fixed \( t > 0, \rho > 0, \)
\[ e(M_{t, \rho}, \delta) \leq \left( \frac{\delta}{c_1} \right)^{t/(t+a)} \rho^{a/(t+a)}. \]  
(6.7)

It is known that the above estimate for \( e(M_{t, \rho}, \delta) \) is sharp (cf. Vainikko [21]). In view of the above observations, an algorithm is called an optimal order yielding algorithm with respect to \( M_{t, \rho} \) and the assumption (2.18), if it yields an approximation \( \tilde{x} \) corresponding to the data \( \tilde{y} \) with \( \|y - \tilde{y}\| \leq \delta \) satisfying
\[ \|\hat{x} - \tilde{x}\| = O(\delta^{t/(t+a)}), \ x \in H_t. \]  
(6.8)

Clearly, Corollary 5.8 shows that if \( h = O(\delta) \) and if \( \max\{0, 1 - a\} < t \leq s \) and \( \tau \) is large enough such that
\[ \gamma + \frac{s}{2} \left[ 1 - \frac{1}{t + a} \right] \geq \frac{1}{\tau + 1}, \]  
(6.9)
then we obtain the optimal order.

7. Applications. For \( r \geq 2 \), denote by \( S_h \) the space of \( r \)th-order splines on the uniform mesh of width \( h = 1/n \), that is, \( S_h \) consists of functions in \( C^{r-1}[0,1] \) which are piecewise polynomials of degree \( r - 2 \). For positive integers \( s \), let \( H^s \) denote the Sobolev space of functions \( u \in C^{s-1}[0,1] \) with \( u^{s-1} \) absolutely continuous and the norm \( \|u\|_{H^s} \) defined by
\[ \|u\|_{H^s} = \left( \sum_{i=1}^{s} \|u^{(i)}\|^2 \right)^{1/2}, \ u \in H^s. \]  
(7.1)
Then $S_h$ is a finite-dimensional subspace of $H^{r-1}$ which has the following well-known approximation property (cf. [1]): for $u \in H^s$, $s \in \mathbb{N}$, there is a constant $\kappa$ (independent of $h$) such that

$$\inf_{\varphi \in S_h} \| u - \varphi \|_{H^j} \leq \kappa h^{\min(s,r)-j} \| u \|_{H^s}, \quad u \in H^s, \ j \in \{0,1\},$$

so that assumption (2.32) is satisfied. We take $L$ as in (2.19), that is,

$$Lx := \sum_{j=1}^{\infty} j^2 \langle x, u_j \rangle u_j,$$

(7.3)

where $u_j(t) := \sqrt{2} \sin(j\pi t)$, $j \in \mathbb{N}$, with domain of $L$ as

$$D(L) := \left\{ x \in L^2[0,1] : \sum_{j=1}^{\infty} j^4 \left| \langle x, u_j \rangle \right|^2 < \infty \right\}.$$

(7.4)

In this case, $(H_t)_{t \in \mathbb{R}}$ is given as in (2.21). It can be seen that $H_t = L^2[0,1]$ for every $u \in L^2[0,1]$, and for $s \in \mathbb{N}$, $H_t \subset H^s$.

Now, let $A : L^2[0,1] \to L^2[0,1]$ be a positive selfadjoint operator. Then we have

$$\| A(I - P_h) \| = \| (I - P)A \| = \sup_{\| u \| \leq 1} \inf_{\varphi \in S_h} \| Au - \varphi \|.$$

(7.6)

Hence, by (7.2),

$$\| A(I - P_h) \| \leq \kappa h^{\min(s,r)} \sup_{\| u \| \leq 1} \| Au \|_{H^s}.$$

(7.7)

From the above inequality it is clear that if $Au \in H_s$ for every $u \in L^2[0,1]$, and if $A : L^2[0,1] \to H_s$ is a bounded operator, then there exists a constant $\hat{c}$ such that

$$\| A(I - P_h) \| \leq \kappa \hat{c} h^{\min(s,r)}$$

(7.8)

so that (5.2) is satisfied.

Now, we consider the case of an integral operator, namely (2.4), having all its eigenvalues nonnegative, and $k(\xi, t) = k(t, \xi)$ for all $(\xi, t) \in [0,1] \times [0,1]$ is such that it is differentiable $s$ times with respect to the variable $\xi$ with its $s$th derivative lying in $L^2[0,1]$. For example, the integral operator may be the one associated with the backward heat equation problem considered in Section 2.

Now,

$$\frac{d^i}{d\xi^i}(Au)(\xi) = \int_0^1 \frac{\partial^i k(\xi,t)}{\partial \xi^i} u(t) dt$$

(7.9)
so that
\[ \|Au\|_{H^s} \leq \|k\|_{0,s} \|u\| \] with
\[ \|k\|_{0,s} = \sum_{i=0}^{s} \int_0^1 \int_0^1 \left| \frac{\partial^{i} k(t,\xi)}{\partial \xi^i} \right|^2 dt \, d\xi. \] (7.10)

Thus we get (7.8) with \( \hat{c} = \|k\|_{0,s} \).

Special Issue on
Intelligent Computational Methods for Financial Engineering

Call for Papers

As a multidisciplinary field, financial engineering is becoming increasingly important in today’s economic and financial world, especially in areas such as portfolio management, asset valuation and prediction, fraud detection, and credit risk management. For example, in a credit risk context, the recently approved Basel II guidelines advise financial institutions to build comprehensible credit risk models in order to optimize their capital allocation policy. Computational methods are being intensively studied and applied to improve the quality of the financial decisions that need to be made. Until now, computational methods and models are central to the analysis of economic and financial decisions.

However, more and more researchers have found that the financial environment is not ruled by mathematical distributions or statistical models. In such situations, some attempts have also been made to develop financial engineering models using intelligent computing approaches. For example, an artificial neural network (ANN) is a nonparametric estimation technique which does not make any distributional assumptions regarding the underlying asset. Instead, ANN approach develops a model using sets of unknown parameters and lets the optimization routine seek the best fitting parameters to obtain the desired results. The main aim of this special issue is not to merely illustrate the superior performance of a new intelligent computational method, but also to demonstrate how it can be used effectively in a financial engineering environment to improve and facilitate financial decision making. In this sense, the submissions should especially address how the results of estimated computational models (e.g., ANN, support vector machines, evolutionary algorithm, and fuzzy models) can be used to develop intelligent, easy-to-use, and/or comprehensible computational systems (e.g., decision support systems, agent-based system, and web-based systems).

This special issue will include (but not be limited to) the following topics:

- **Application fields**: asset valuation and prediction, asset allocation and portfolio selection, bankruptcy prediction, fraud detection, credit risk management
- **Implementation aspects**: decision support systems, expert systems, information systems, intelligent agents, web service, monitoring, deployment, implementation

Authors should follow the Journal of Applied Mathematics and Decision Sciences manuscript format described at the journal site [http://www.hindawi.com/journals/jamds/](http://www.hindawi.com/journals/jamds/). Prospective authors should submit an electronic copy of their complete manuscript through the journal Manuscript Tracking System at [http://mts.hindawi.com/](http://mts.hindawi.com/), according to the following timetable:
