This paper provides an asymptotic estimate for the expected number of real zeros of a random algebraic polynomial \(a_0 + a_1 x + a_2 x^2 + \cdots + a_{n-1} x^{n-1}\). The coefficients \(a_j (j = 0, 1, 2, \ldots, n - 1)\) are assumed to be independent normal random variables with nonidentical means. Previous results are mainly for identically distributed coefficients. Our result remains valid when the means of the coefficients are divided into many groups of equal sizes. We show that the behaviour of the random polynomial is dictates by the mean of the first group of the coefficients in the interval \((-1, 1)\) and the mean of the last group in \((-\infty, -1) \cup (1, \infty)\).

2000 Mathematics Subject Classification: 60H99, 42Bxx.

1. Introduction. There are many known asymptotic estimates for the expected number of real zeros of polynomials

\[ P_n(x) = \sum_{j=0}^{n-1} a_j x^j, \tag{1.1} \]

with random coefficients \(a_0, a_1, \ldots, a_{n-1}\). These estimates, however, are mainly devoted for the case of identically distributed coefficients, albeit for different classes of distributions. From the pioneer work of Kac [9], it is known that in the normal standard case the expected number of real zeros of \(P_n(x)\), denoted by \(E_n(-\infty, \infty)\), is asymptotic to \((2/\pi) \log n\) as \(n \to \infty\). Later, the error term involved in this asymptotic formula is significantly reduced by Wilkins [12], using a new approach. Also, various cases of dependent coefficients are studied mainly by Sambandham, see, for example, [1, 11].

For a case when the coefficients have a nonzero mean, \(\mu\), it is shown that \(E_n(-\infty, \infty)\) is reduced by half to \((1/\pi) \log n\). In [4], a case when the coefficients are nonidentical is considered. However, they are only permitted to belong to two groups of distributions. In an interesting work, Edelman and Kostlan [3] consider a case of nonidentically distributed coefficients, each having different variances. It is important to note that so far their coefficients are the only type of distribution which increases the order of numbers of real zeros from \(O(\log n)\) to \(O(\sqrt{n})\). In [6], all the coefficients of (1.1) have also different means, but they follow a geometric progression, that is, \(E(a_j) = \mu^j, j = 0, 1, 2, \ldots, n - 1\) for a constant \(\mu\). Recent developments on the subject as well as related works are reviewed in [5].

Here, we assume that the coefficients \(\{a_j\}_{j=0}^{n-1}\) in (1.1) are independent and nonidentically distributed. They are normal random variables, all have variance one and their...
means are divided into groups of equal size. Let \( E(a_j) = \mu_1 \) for \( 0 \leq j \leq n_1 - 1, E(a_j) = \mu_2 \) for \( n_1 \leq j \leq n_2 - 1, \ldots, E(a_j) = \mu_k \) for \( n_{k-1} \leq j \leq n - 1 \), where \( n_1 = \lfloor n/k \rfloor, n_2 = \lfloor 2n/k \rfloor \), and so forth and \( k \) is any constant such that \( 1 < k \leq \gamma/5 \), \( \gamma \) a constant to be defined below. In this work, we impose the conditions that \( \mu_1 \) and \( \mu_k \) are bounded away from zero, that is, \( |\mu_1|/\sqrt{\log n} \to \infty \) and \( |\mu_k|/\sqrt{\log n} \to \infty \) as \( n \to \infty \). Also \( |\mu_j - \mu_{j-1}| \leq c \), where \( c = O(n^{r-5}\log n) = \mu_j^2 \) and \( r \) is defined below. Let \( N_n(\alpha, \beta) \) represent the number of real zero crossings of \( P_n(x) \) on the interval \((\alpha, \beta)\). In these circumstances, we have the following theorem.

**Theorem 1.1.** If the coefficients of \( P_n(x) \) in (1.1) are as outlined above, then the mathematical expectation of the number of zeros of \( P_n(x) \) on various intervals of the real number line, denoted as \( E N_n(\alpha, \beta) \), satisfies

\[
EN_n(0, 1) = O\left(\sqrt{\log n}\right), \quad EN_n(-1, 0) \sim \left(\frac{1}{2\pi}\right)\log n, \quad (1.2)
\]

if \( |\mu_1|\log n)^{1/2} \to \infty \) as \( n \to \infty \) and \( \mu_2, \ldots, \mu_k = o(n^q) \); and

\[
EN_n(-\infty, -1) \sim \left(\frac{1}{2\pi}\right)\log n, \quad EN_n(1, \infty) = O\left(\sqrt{\log n}\right) \quad (1.3)
\]

if \( |\mu_k|\log n)^{1/2} \to \infty \) as \( n \to \infty \) and \( \mu_1, \ldots, \mu_{k-1} = o(n^q) \), where \( q \) is any positive constant.

2. **Proof of the theorem.** We start our proof by noting that in the interval \((0, 1)\)

\[ x^n < x^{n_{k-1}} < \cdots < x^{n_2} < x^{n_1} \leq \exp(-n_1\varepsilon) = n^{-r}, \]

where \( r = \gamma/k \) and \( \varepsilon = n^{-a}, a = 1 - \log \log n^\gamma/\log n \). First, for \( 0 < x < 1 - \varepsilon \) we define and expand the required variances and covariances as follows:

\[
A^2 = \text{var}\{P_n(x)\} = \sum_{j=0}^{n-1} x^{2j} = \frac{1-x^{2n}}{1-x^2} = \frac{1}{1-x^2} + O\left(n^{1-2r}(y \log n)^{-1}\right), \quad (2.1)
\]

\[
B^2 = \text{var}\{P'_n(x)\} = \sum_{j=0}^{n-1} j^2 x^{2j-2} = \frac{(1+x^2)(1-x^{2n})}{(1-x^2)^3} - \frac{2nx^{2n}}{(1-x^2)^2} - \frac{n^2x^{2n-2}}{1-x^2}
\]

\[
= \frac{(1+x^2)}{(1-x^2)^3} + O\{n^{5-2r}(y \log n)^{-3}\}, \quad (2.2)
\]

\[
C = \text{cov}\{P_n(x), P'_n(x)\} = \sum_{j=0}^{n-1} jx^{2j-1} = \frac{x(1-x^{2n})}{(1-x^2)^2} - \frac{nx^{2n-1}}{1-x^2}
\]

\[
= \frac{x}{(1-x^2)^2} + O\{n^{3-2r}(y \log n)^{-2}\}. \quad (2.3)
\]

The expected values that give this problem its special properties are defined as

\[
m = E\{P_n(x)\}, \quad m' = E\{P'_n(x)\}. \quad (2.4)
\]
These definitions can easily be expanded to show that

\[
m = \mu_1 \sum_{j=0}^{n_1-1} x^j + \mu_2 \sum_{j=n_1}^{n_2-1} x^j + \cdots + \mu_k \sum_{j=n_{k-1}}^{n_{k-1}-1} x^j,
\]

\[
m' = \mu_1 \sum_{j=0}^{n_1-1} jx^{j-1} + \mu_2 \sum_{j=n_1}^{n_2-1} jx^{j-1} + \cdots + \mu_k \sum_{j=n_{k-1}}^{n_{k-1}-1} jx^{j-1}.
\]

These in turn give

\[
\begin{align*}
|m - \frac{\mu_1(1-x^n)}{1-x}| & \leq \frac{c x^{n_1}}{(1-x)(1-x^{n_1})}, \\
|m' - \left[ \frac{\mu_1(1-x^n)}{(1-x)^2} - \frac{\mu_1 x^{2n_1}}{x(1-x)} \right]| & \leq c x^{n_1} \left\{ 1 - (x^{n_1})^{k_1-1} - (1-x^{n_1})(k_1-1)(x^{n_1})^{k_1-1} \\
& + (1-x) \left( x^{n_1} \left[ (1-x^{n_1})^{k_1-1} - (1-x^{n_1})(k_1-1)x^n \right] \right. \\
& \left. + (1-x) \left[ n_1 - (k_1-1)n_1(x^{n_1})^{k_1-2} \right] \right\} \times \frac{1}{(1-x)^2(1-x^{n_1})}. 
\end{align*}
\]

To highlight the dominant terms on \(0 < x < 1 - \varepsilon\), we can write \(m\) and \(m'\) as

\[
m = \frac{\mu_1}{1-x} + O\{(|\mu_1| + c)n^{1-r}y\log n\}, \tag{2.7}
\]

\[
m' = \frac{\mu_1}{(1-x)^2} + O\{(|\mu_1| + c)n^{2-r}y\log n\}. \tag{2.8}
\]

Kac [9] obtained a formula for the average number of real zeros of a polynomial of the form (1.1), where the coefficients are independent standard normal random variables. Hammersley [8] in his work on the zeros of polynomials with generally distributed coefficients, and Cramér and Leadbetter [2] in their study of nonstationary random processes, developed the findings of Kac [9] and Rice [10] for more general situations. From these, Farahmand and Hannigan [7] obtained an expression of the Kac-Rice formula for independent identically distributed normal coefficients having nonzero mean. Although in this case we study a polynomial that has nonidentically distributed coefficients, we can utilise the same Kac-Rice formula. Hence, from [7],

\[
\begin{align*}
\text{EN}_n(\alpha, \beta) &= \int_{\alpha}^{\beta} \left( \frac{\Delta}{\pi A^2} \right) \exp \left\{ -\frac{(A^2 m'^2 + B^2 m^2 - 2C m m')}{2\Delta^2} \right\} dx \\
&\quad + \int_{\alpha}^{\beta} \left( \frac{\sqrt{A^2 m'^2 - C m}}{2\pi} \right) \left( A^2 m' - C \right) A^{-3} \exp - \left( \frac{m^2}{2A^2} \right) \times \text{erf} \left( \frac{[A^2 m' - C m]}{A\Delta \sqrt{2}} \right) dx \\
&= I_1(\alpha, \beta) + I_2(\alpha, \beta),
\end{align*}
\]

(2.9)
where $\Delta^2 = A^2B^2 - C^2$. By (2.1) to (2.8), we can establish that

$$
\frac{\Delta}{A^2} = \frac{1}{1 - x^2} + O\left\{ n^{4-2r} (\gamma \log n)^{-4} \right\},
$$

$$
\frac{(A^2m'^2 + B^2m'^2 - 2CMm')}{2\Delta^2} = \frac{\mu_1^2 (1 + x)}{1 - x} + O\left\{ \frac{\mu_1 (|\mu_1| + c)}{nr^{-1}} \right\}.
$$

These, in turn, give the value of $I_1(0, 1 - \varepsilon)$ in (2.9) as

$$
I_1(0, 1 - \varepsilon) = \int_0^{1 - \varepsilon} \left( \frac{\Delta}{\pi A^2} \right) \exp \left\{ - \frac{(A^2m'^2 + B^2m'^2 - 2CMm')}{2\Delta^2} \right\} dx
$$

$$= \pi^{-1} \int_{1 - \varepsilon}^{1 - x^2} \left[ \exp \left\{ - \frac{\mu_1^2 (1 + x)}{1 - x} \right\} + O\left\{ \frac{\mu_1 (|\mu_1| + c)}{nr^{-1}} \right\} \right] dx
$$

$$\leq \pi^{-1} \int_0^{1 - \varepsilon} (1 - x^2)^{-1} \exp \left\{ - \frac{\mu_1^2}{1 - x} \right\} dx.
$$

Putting $t = 1/(1 - x)$ gives

$$I_1(0, 1 - \varepsilon) \leq \pi^{-1} \int_1^{1/\varepsilon} \exp (-\mu_1^2 t) dt = \frac{\exp (-\mu_1^2) - \exp (-\mu_1^2/\varepsilon)}{\pi \mu_1^2} \leq \exp (-\mu_1^2).
$$

Therefore, for $\mu_1 \neq 0$ and bounded such that $|\mu_1| (\log n)^{1/2} \to \infty$ as $n \to \infty$, we have

$$I_1(0, 1 - \varepsilon) = O\left( \sqrt{\log n} \right).
$$

In the following, we show that for all values of $\mu$ under consideration, the expected number of real zeros in the interval $(1 - \varepsilon, 1)$ is negligible for large $n$. Since, from (2.1)–(2.3),

$$\Delta^2 = (1 - x^2)^2 (1 - x^2)^{-4} \left\{ 1 - \frac{n^2 x^{2n-2} (1 - x^2)^2}{(1 - x^{2n})^2} \right\},
$$

we have

$$\frac{\Delta}{A^2} = \left\{ 1 - \frac{n^2 x^{2n-2} (1 - x^2)^2}{(1 - x^{2n})^2} \right\}^{1/2} \times \frac{1}{1 - x^2}.
$$

This enables us to establish the inequality

$$\frac{\Delta}{A^2} < \sqrt{\frac{(2n-1)}{1 - x}}
$$

(2.16)
on the interval \((1 - \varepsilon, 1)\) for all sufficiently large \(n\). Therefore, we find

\[
I_1(1 - \varepsilon, 1) < \int_{1-\varepsilon}^{1} \left( \frac{\Delta}{\pi A^2} \right) dx = o\left(\sqrt[4]{\log n}\right). \tag{2.17}
\]

To evaluate \(I_2(0, 1)\) we note that since \((d/dx)(m/A) = A^{-3}(A^2m' - Cm)\) and \(\text{erf}(x) \leq \sqrt{\pi}/2\), we have

\[
I_2(0, 1) \leq \left( \frac{1}{\sqrt{2\pi}} \right) \int_{\mu_1}^{\zeta} \exp\left( - \frac{u^2}{2} \right) du = O(1), \tag{2.18}
\]

where \(u = m/A\) and \(\zeta = (\sqrt{n}/k) \sum_{j=1}^{k} \mu_j\). Thus, by (2.13), (2.17), and (2.18), we have

\[
\text{EN}_n(0, 1) = O\left(\sqrt{\log n}\right). \tag{2.19}
\]

Given that \(P_n(x) = x^{n-1} \sum_{j=0}^{n-1} a_{n-j-1} x^{-j} = x^{n-1} P_n^*(y)\), \(y = 1/x\), we can state that for each zero of \(P_n(x)\) in \((0, 1)\) or \((-1, 0)\) there is a corresponding zero of \(P_n^*(x)\) in \((1, \infty)\) or \((-\infty, -1)\). We interchange \(\mu_1\) and \(\mu_k\), \(\mu_2\), and \(\mu_{k-1}\), and so forth, and replace \(k\) with \(k/(k-1)\) in \(P_n^*(x)\). The distribution of \(P_n^*(x)\) is therefore identical to that of \(P_n(x)\). Let \(N_n^*(\alpha, \beta)\) denote the number of zeros of \(P_n^*(x)\) in the interval \((\alpha, \beta)\). Therefore, we have \(\text{EN}_n(0, 1) = \text{EN}_n^*(1, \infty)\), and \(\text{EN}_n(-1, 0) = \text{EN}_n^*(-\infty, -1)\).

To find \(\text{EN}_n(-1, 0)\), we let \(y = -x\). This gives

\[
I_1(-1 + \varepsilon, 0) = \pi^{-1} \int_{0}^{1-\varepsilon} (1 - y^2)^{-1} \left[ \exp\left\{ - \frac{\mu_1^2 (1 - y)}{1 + y} \right\} + O\left\{ \frac{\mu_1 (|\mu_1| + \varepsilon)}{n^{r-1}} \right\} \right] dy \tag{2.20}
\]

\[
\times [1 + O\{n^{4-2r}(y \log n)^{-4}\}].
\]

We can say that

\[
I_1(-1 + \varepsilon, 0) \leq \pi^{-1} \int_{0}^{1-\varepsilon} (1 - y^2)^{-1} dy \leq \left( \frac{1}{2\pi} \right) \log n. \tag{2.21}
\]

It is also true to say that

\[
I_1(-1 + \varepsilon, 0) > \pi^{-1} \int_{0}^{1-\varepsilon} \left[ 2(1 - y) \right]^{-1} \exp\{2\mu_1^2 (1 - y)\} dy \tag{2.22}
\]

Putting \(t = 2\mu_1^2 (1 - y)\) gives

\[
I_1(-1 + \varepsilon, 0) > \left( \frac{1}{2\pi} \right) \int_{2\mu_1^2}^{2\mu_1^2} - \left( \frac{1}{t} \right) \exp(-t) dt = \left( \frac{1}{2\pi} \right) \int_{2\mu_1^2}^{2\mu_1^2} \frac{e^{-t}}{t} dt \tag{2.23}
\]

\[
= \left( \frac{1}{2\pi} \right) \int_{2\mu_1^2}^{2\mu_1^2} \frac{dt}{t} - \left( \frac{1}{2\pi} \right) \int_{2\mu_1^2}^{2\mu_1^2} \frac{1}{t} e^{-t} dt.
\]
Upon integration, we obtain

\[ I_1(-1 + \varepsilon, 0) > \left( \frac{1}{2\pi} \right) \log n + O(\log \log n). \]  

(2.24)

Thus, by (2.21) and (2.24), we find

\[ I_1(-1 + \varepsilon, 0) \sim \left( \frac{1}{2\pi} \right) \log n. \]  

(2.25)

By letting \( y = -x \), we can establish, in a manner similar to (2.17), that

\[ I_1(-1, -1 + \varepsilon) = o\left( \sqrt{\log n} \right). \]  

(2.26)

As regards \( I_2(-1, 0) \), we find that

\[ I_2(-1, 0) \leq \left( \frac{1}{\sqrt{2\pi}} \right) \int_{\mu_1}^{\mu} \exp \left( -\frac{u^2}{2} \right) du, \]  

(2.27)

when \( n_1 \) is even, or for \( \tau = \sum_{j=1}^{k} (-1)^{j+1} \mu_j \),

\[ I_2(-1, 0) \leq \left( \frac{1}{\sqrt{2\pi}} \right) \int_{\tau/\sqrt{n}}^{\mu_1} \exp \left( -\frac{u^2}{2} \right) du \]  

(2.28)

when \( n_1 \) is odd. Thus,

\[ I_2(-1, 0) \leq \frac{1}{2}. \]  

(2.29)

We can conclude from (2.25), (2.26), and (2.29) that

\[ \text{EN}_n(-1, 0) \sim \left( \frac{1}{2\pi} \right) \log n. \]  

(2.30)

This completes the proof of the theorem. The result of this paper is similar to the findings of [4] and establishes the predominant influence of the means of the first and last groups of random coefficients on the average number of zeros of the polynomial. An area of future interest regarding random algebraic polynomials would be to ascertain how small the first and last groups of coefficients can be before the means of other groups become significant.

Special Issue on Modeling Experimental Nonlinear Dynamics and Chaotic Scenarios

Call for Papers

Thinking about nonlinearity in engineering areas, up to the 70s, was focused on intentionally built nonlinear parts in order to improve the operational characteristics of a device or system. Keying, saturation, hysteretic phenomena, and dead zones were added to existing devices increasing their behavior diversity and precision. In this context, an intrinsic nonlinearity was treated just as a linear approximation, around equilibrium points.

Inspired on the rediscovering of the richness of nonlinear and chaotic phenomena, engineers started using analytical tools from “Qualitative Theory of Differential Equations,” allowing more precise analysis and synthesis, in order to produce new vital products and services. Bifurcation theory, dynamical systems and chaos started to be part of the mandatory set of tools for design engineers.

This proposed special edition of the Mathematical Problems in Engineering aims to provide a picture of the importance of the bifurcation theory, relating it with nonlinear and chaotic dynamics for natural and engineered systems. Ideas of how this dynamics can be captured through precisely tailored real and numerical experiments and understanding by the combination of specific tools that associate dynamical system theory and geometric tools in a very clever, sophisticated, and at the same time simple and unique analytical environment are the subject of this issue, allowing new methods to design high-precision devices and equipment.

Authors should follow the Mathematical Problems in Engineering manuscript format described at http://www.hindawi.com/journals/mpe/. Prospective authors should submit an electronic copy of their complete manuscript through the journal Manuscript Tracking System at http://mts.hindawi.com/ according to the following timetable:
