(Received November 2, 1988 and in revised form December 12, 1988)

ABSTRACT: If \( n \geq 1 \), let the \( n^{th} \) row of an infinite triangular array consist of entries

\[
B(n, j) = \frac{n}{n-j} (n-j), \quad 0 \leq j \leq \left[ \frac{n}{2} \right]
\]

We develop some properties of this array, which was discovered by Vieta. In addition, we prove some irreducibility properties of the family of polynomials \( V_n(x) = \sum_{j=0}^{\left[ \frac{n}{2} \right]} (-1)^j B(n, j) x^{n-2j} \).

These polynomials, which we call Vieta polynomials, are related to Chebychev polynomials of the first kind.

KEY WORDS AND PHRASES: Binomial coefficient, Fibonacci number, Lucas number, irreducible polynomial, Chebychev polynomial.

1980 AMS SUBJECT CLASSIFICATION CODE: 10A35, 10A40

1. INTRODUCTION.

For any \( n \geq 1 \), we let the \( n^{th} \) row of an infinite left adjusted triangular array consist of the entries

\[
B(n, j) = \frac{n}{n-j} (n-j), \quad 0 \leq j \leq \left[ \frac{n}{2} \right]
\]

where Horadam [1] attributes (1.1) to Lucas [2]. The array in question is

\[
\begin{array}{cccccccccc}
1 \\
1 & 2 \\
1 & 3 \\
1 & 4 & 2 \\
1 & 5 & 5 \\
1 & 6 & 9 & 2 \\
1 & 7 & 14 & 7 \\
1 & 8 & 20 & 16 & 2 \\
1 & 9 & 27 & 30 & 9 \\
1 & 10 & 35 & 50 & 25 & 2 \\
\end{array}
\]
This array was first used by Vieta [3], where we find

\[ 2 \cos n\theta = \sum_{j=0}^{[n/2]} (-1)^j B(n,j) (2 \cos \theta)^{n-2j} \] (1.3)

The array has also been studied by Lucas [2] who observed (1.2) as well as

\[ x^n + y^n = \sum_{j=0}^{[n/2]} (-1)^j B(n,j) (x+y)^{n-2j} \] (1.4)

which is attributed to Lagrange by Ribenboim [4, p. 45],

\[ L_{kn} = \sum_{j=0}^{[n/2]} (-1)^j (k+1) B(n,j) L_k^{n-2j} \] (1.5)

and for odd \( n \)

\[ F_{kn} = \sum_{j=0}^{[n/2]} (-1)^{k+1} F_k^{(n-1)/2} F_k^{n-2j} \] (1.6)

where \( L_m \) and \( F_m \) are respectively the \( m^{th} \) Lucas and Fibonacci numbers. Equations (1.5) and (1.6) readily follow by induction on \( n \). In Hoggatt [5], we find

\[ L_n = \sum_{j=0}^{[n/2]} B(n,j) \] (1.7)

which follows directly from (1.5) with \( k=1 \), and

\[ B(n,j) = B(n-1,j) + B(n-2,j-1), n \geq 3 \text{ and } 0 \leq j \leq \lfloor n/2 \rfloor \] (1.8)

where it is assumed that a zero is used whenever a number in the array does not appear.

Equations (1.4), (1.7) and (1.8) illustrate that the \([B(n,j)]\) have properties similar to those of the binomial coefficients.

In this paper, we develop additional properties associated with this array as well as prove some irreducibility properties of the family of polynomials

\[ V_n(x) = \sum_{j=0}^{[n/2]} (-1)^j B(n,j)x^{n-2j} \] (1.9)

which we call Vieta polynomials.

Jacobstahl [6] proved that \( \{V_n(x)\} \) is a family of permutable polynomials, that is, \( V_m(V_n(x)) = V_n(V_m(x)) = V_{mn}(x) \) for all natural numbers \( m,n \). He also proved that if \( \{f_n(x)\} \) is a family of permutable polynomials such that the degree of \( f_n(x) \) is \( n \) for all \( n \), then \( f_n(x) \) is similar to either \( V_n(x) \) or \( x^n \), that is, there exists a polynomial \( g(x) = ax + b \) such that \( f_n(x) = g(x) \ast V_n(x) \ast g^{-1}(x) \) or \( f_n(x) = g(x) \ast x^n \ast g^{-1}(x) \), where \( \ast \) denotes composition. Jacobstahl also noted that the Vieta polynomials are related to the Chebychev polynomials of the first kind (denoted \( T_n(x) \)) by the identity:

\[ V_n(x) = 2T_n\left(\frac{x}{2}\right) \] (1.10)

In addition, he gave an inductive definition for the \( V_n(x) \), namely:

\[ V_0(x) = 2, V_1(x) = x, V_n(x) = xV_{n-1}(x) - V_{n-2}(x), n \geq 2 \] (1.11)
The Lucas polynomials, defined by Bicknell in [7] as

\[ L_0(x) = 2, \quad L_1(x) = x, \quad L_n(x) = xL_{n-1}(x) + L_{n-2}(x), \quad n \geq 2 \]  

are not permutable and satisfy

\[ L_n(x) = \sum_{j=0}^{[\frac{1}{2}n]} B(n, j)x^{n-2j} \]  

(1.13)

as well as

\[ V_n(ix) = i^n L_n(x) \]  

(1.14)

where \( i = (-1)^{\frac{1}{2}} \).

In conclusion, we point out that Bergum and Hoggatt [8] prove that if \( k \geq 1 \) and \( p \) is an odd prime, then \( L_k(x) \) and \( L_p(x)/x \) are irreducible over the rationals. Their proofs adapt easily to show that the same properties hold respectively for \( V_k(x) \) and \( V_p(x)/x \). In this paper, we generalize the latter result. Specifically, we prove that if \( m \geq 1 \), \( p \) and \( n \) are odd, and \( p \) is prime, then both \( V_p(x)/V_n(x) \) and \( V_{3(2m)}(x)/V_{2m}(x) \) are irreducible over the rationals.

2. PRELIMINARIES.

Below is a list of identities, some of which are used to develop the results in section 3 of this paper, while others are of interest in their own right.

Using (1.9) and (1.10) in Rivlin [9], with (1.10), we have

\[ B(n, j) = \frac{1}{2^n - 1 - 2j} \sum_{j=0}^{[\frac{1}{2}j]} (n/k) \]  

(2.1)

Letting \( z = y^{-1} = e^{\theta} \) in (1.4), we have

\[ 2 \cosh n\theta = \sum_{j=0}^{[\frac{1}{2}n]} (-1)^j B(n, j)(2 \cosh \theta)^{n-2j} \]  

(2.2)

while

\[ o_p(B(n, j)) \geq o_p(n) - o_p(j) \]  

(2.3)

where \( o_p(n) = h \) if \( p^h \mid n, p^{h+1} \nmid n, h \geq 0 \), follows directly from (1.2) and the laws of exponents.

In Cohn [10, p. 156], we find

\[ x^2 - 5y^2 = -4 \quad \text{if there exists an odd } k \text{ such that} \]

\[ x = L_k, \quad y = F_k \]

while

\[ V_{mn}(x) = V_m(V_n(x)) \quad \text{for all } m, n \]  

(2.5)

appears in [6].

Letting \( z = y^{-1} = e^{i\theta} \) in (1.4), we have

\[ 2 \cos n\theta = \sum_{j=0}^{[\frac{1}{2}n]} (-1)^j B(n, j)(2 \cos \theta)^{n-2j} \]  

(2.6)
Using (1.9) with (2.6) and (2.2), we obtain
\[ V_n(2 \cos \theta) = 2 \cos n\theta \] (2.7)
and
\[ V_n(2 \cosh \theta) = 2 \cosh n\theta \] (2.8)

Finally, we observe that it is easy to show that
\[ 5F_{4m+1} - L_{4m+1} \equiv \pm 4 \pmod{10}, m \geq 0 \] (2.9)

3. THE MAIN RESULTS.

We begin with some divisibility properties of the \( B(n, j) \).

**THEOREM 1.** If \( 1 \leq j \leq \lfloor \frac{n-1}{2} \rfloor, p^h \mid n, \) and \( p^h \mid B(n, j) \), then \( p^h \mid B(n, j) \).

**PROOF.** This follows from the hypothesis and (2.3).

**THEOREM 2.** If \( 1 \leq j \leq \lfloor \frac{n}{2} \rfloor \) and \( (n, j) = 1 \), then \( n \mid B(n, j) \).

**PROOF.** Equation (1.2) implies \( n \mid jB(n, j) \). The conclusion now follows from the hypothesis and Euclid’s Lemma.

**COROLLARY 1.** If \( p \) is an odd prime and \( 1 \leq j \leq \lfloor \frac{n-1}{2} \rfloor \) there exists a prime, \( p \), such that \( p \mid n \) and \( p \mid B(n, j) \).

**PROOF.** This follows from Theorem 2.

**THEOREM 3.** For all \( j \) such that \( 1 \leq j \leq \lfloor \frac{n-1}{2} \rfloor \) there exists a prime, \( p \), such that \( p \mid n \) and \( p \mid B(n, j) \).

**PROOF.** Assume the contrary. Then there exists \( j \) such that \( 1 \leq j \leq \lfloor \frac{n-1}{2} \rfloor \) and for all primes \( p \) where \( p \mid n \) we have \( p \mid B(n, j) \), so \( p \mid B(n, j) = 0 \). But then (2.3) implies \( p^h \mid B(n, j) \). Since this inequality holds for all prime divisors of \( n \), we have \( n \mid j \), which is contrary to our hypothesis.

**COROLLARY 2.** If \( 1 \leq j \leq \lfloor \frac{n}{2} \rfloor \), then \( p \mid B(p^k, j) \).

**PROOF.** This follows from Theorem 3.

**THEOREM 4.** Let \( p \) be an odd prime. If \( 1 \leq j \leq p^h \), then \( p \mid B(2p^k, j) \). If \( 1 \leq j \leq 2p^h \) and \( j \neq p^h \), then \( p \mid B(4p^k, j) \).

**PROOF.** The hypothesis implies that \( p^h(j) \leq k-1 \), so the conclusions follow from (2.3).

**THEOREM 5.** If \( n \mid B(n, p) \).

**PROOF.** The hypothesis implies that \( n = k^p \) and \( p \mid k \). Since (1.2) implies that \( B(n, p) = B(kp, p) = p \frac{k^p - 1}{k^p - 1} \), the conclusion follows directly from the fact that \( p \mid p \frac{k^p - 1}{k^p - 1} \).

The next result provides an analog to the identity \( \sum_{j=0}^{\frac{n}{2}} (-1)^j \binom{n}{j} = 0 \).

**THEOREM 6.** \( \sum_{j=0}^{\lfloor \frac{n}{2} \rfloor} (-1)^j B(n, j) = \begin{cases} 2 & \text{if } n \equiv 0 \pmod{6}, \ 1 & \text{if } n \equiv \pm 1 \pmod{6}, \ -1 & \text{if } n \equiv \pm 2 \pmod{6}, \ -2 & \text{if } n \equiv 3 \pmod{6} \end{cases} \)

**PROOF.** This follows from (1.3) with \( \theta = \pi/3 \).

The next theorem locates the largest entry or entries in the \( n \)th row of Vieta’s triangular array.

**THEOREM 7.** If \( 0 \leq j \leq \lfloor \frac{n}{2} \rfloor \), let \( r = (5n + 6 - (5n^2 - 4)^{1/2})/10 \).

If \( r \) is not an integer, then \( B(n, [r]) > B(n, j) \) for all \( j \neq [r] \).

If \( r \) is an integer, then \( B(n, r - 1) = B(n, r) > B(n, j) \) for all \( j \neq r - 1, r \).
PROOF. Let \( f_n(j) = \frac{B(n,j)}{B(n,j-1)} \) where \( 1 \leq j \leq \lfloor \frac{1}{2}n \rfloor \). Equation (1.2) implies that
\[
f_n(j) = \frac{n(n-j-1)!}{j!(n-2j)!} \cdot \frac{(j-1)!(n-2j+2)!}{(n-j+1)!(n-2j+2)!} = \frac{(n+1-2j)(n+2-2j)}{j(n-j)}.
\]

Now \( B(n,j) \), considered as a function of \( j \) for a fixed value of \( n \), is increasing, decreasing, or not changing accordingly as \( f_n(j) \) is greater than, less than, or equal to 1. These possibilities occur accordingly as \( 5j^2 - (5n+6)j + (n+1)(n+2) \) is positive, negative, or zero, or accordingly as \( 1 \leq j < r, j = r, \) or \( r < j \leq \lfloor \frac{1}{2}n \rfloor \).

If \( r \) is not an integer, then \( B(n,j) \) is increasing for \( 1 \leq j \leq \lfloor r \rfloor \) and decreasing for \( \lfloor r \rfloor < j \leq \lfloor \frac{1}{2}n \rfloor \). Hence, \( B(n,j) \) assumes a unique maximum at \( j = \lfloor r \rfloor \). If \( r \) is an integer, then \( B(n,r-1) = B(n,r) \) and \( B(n,j) \) is increasing for \( 1 \leq j < r-1 \), decreasing for \( r < j \leq \lfloor \frac{1}{2}n \rfloor \). Hence, \( B(n,j) \) assumes its maximum value when \( j = r-1 \) or \( r \).

The following two theorems give necessary and sufficient conditions for \( r \) to be an integer.

**THEOREM 8.** \( 5F_{4m+1} - L_{4m+1} + 6 \)/10 = \( F_{2m+1}^2 \).

**PROOF.** This follows directly by induction, or by using Binet's formulas for \( F_n \) and \( L_n \).

**THEOREM 9.** Let \( r = (5n+6 - (5n^2 - 4)^{1/2})/10 \). Then \( r \) is an integer if there exists \( m \) such that \( n = F_{4m+1} \) and \( r = F_{2m+1}^2 \).

**PROOF.** If \( r \) is an integer, then \( (5n^2 - 4)^{1/2} = t \) is an integer. Therefore, \( t^2 - 5n^2 = -4 \) and (2.4) implies that there exists an odd \( k \) such that \( t = L_k, n = F_k \). Since \( r \) is an integer, we must also have \( 5F_k - L_k \equiv 4 \pmod{10} \). Since (2.9) implies that \( k = 4m+1 \), we have \( r = (5F_{4m+1} - L_{4m+1} + 6)/10 \). Theorem 8 now implies that \( r = F_{2m+1}^2 \). The converse clearly holds.

We now turn our attention to the Viete polynomials.

**THEOREM 10.** If \( n \) is odd and \( p \) is an odd prime, then \( V_{pn}(x)/V_n(x) \) is irreducible over the rational numbers.

**PROOF.** Using (2.5) and (1.9), we see that
\[
V_{pn}(x) = V_p(V_n(x)) = \sum_{j=0}^{\frac{1}{2}(p-1)} (-1)^j \frac{p-j}{p-j} V_n(x)^{p-1} - 2j = \frac{1}{2}(p-1) \sum_{j=0}^{\frac{1}{2}(n-1)} (-1)^j \frac{p-j}{p-j} (\sum_{i=0}^{n-1} (-1)^{n-1} x^n - 2\tau)^{p-1} - 2j.
\]

The lead term is \( x^{(p-1)n} \) while all other variable terms are divisible by \( p \). The constant term is \( p^{(p-1)} \). Therefore, the conclusion follows from the Eisenstein criterion.

One may conjecture that the conclusion of Theorem 10 is also valid when \( n \) is even, but this difficult to prove.

**LEMMA 1.** \( V_{2mp}(x)/V_{2m}(x) = 1 \) if \( p \) is odd.

**PROOF.** Equation (2.6) implies that \( V_{2m}(0) = V_{2m}(2 \cos \frac{\pi}{m}) = 2 \cos m\pi = 2(-1)^m \). Therefore, \( V_{2mp}(0)/V_{2m}(0) = 2(\frac{1}{2}n)^{p-1} \). Since \( 2 \) is even, we have \( (-1)^{p-1} = 1 \).

**REMARK.** Lemma 1 says that constant term in \( V_{pn}(x)/V_n(x) \) is 1 if \( n \) is even, so that Eisenstein criterion is not immediately applicable to prove irreducibility.

**THEOREM 11.** Let \( g_m(x) = V_{2m}(x) - 1 \), where \( m \geq 0 \). Then \( g_m(x) \) is irreducible over the rational numbers.

**PROOF.** (Induction on \( m \)) For \( m = 0, g_0(x) = V_1(x) - 1 = x - 1 \), which is irreducible. If \( m \geq 1 \), let \( h_m(y) = g_m(y + 1) = V_{2m}(y + 1) - 1 \). Then
\[
h_m(0) = g_m(1) = V_{2m}(1) - 1 = V_{2m}(2 \cos \frac{\pi}{3}) - 1 = 2 \cos (2^m \pi/3) - 1 = 2(\frac{1}{2}) - 1 = -2.
\]
But
\[ h_1(y) = V_2(y+1) - 1 = (y+1)^2 - 2 - 1 = y^2 + 2y - 2, \]
and
\[ h_m(y) = \sum_{j=0}^{2m-1} (-1)^j B(2^m, j)(y+1)^{2j} = y^{2m} + \sum_{k=1}^{2m-1} c_{k, m} y^{2m-k} - k - 2. \]

We claim that each coefficient \( c_{k, m} \) is even. To prove this, we note that
\[ h_{m+1}(y) = V_{2m+1}(y+1) - 1 = V_2(2m(y+1)) - 1 = V_2(h_m(y) + 1) - 1 = (h_m(y) + 1)^2 - 3 \]
\[ = y^{2m} + \sum_{k=1}^{2m+1} c_{k, m} y^{2m-k} - (k - 1)^2 - 3 = y^{2m+1} + \sum_{k=1}^{2m+1} c_{k, m} y^{2m+1-k} - k - 2. \]

Since (by induction hypothesis) all the \( c_{k, m} \) are even, it follows that all the \( c_{k, m+1} \) are even. Therefore, \( h_m(y) \) is irreducible over the rational numbers by the Eisenstein criterion, with \( p=2 \).

Letting \( x = y+1 \), we have \( g_m(x) \) is irreducible over the rationals for all \( m \geq 0 \).

**THEOREM 12.** If \( f_m(x) = V_{3(2m)}(x)/V_{2m}(x) \) where \( m \geq 0 \), then \( f_m(x) \) is irreducible over the rationals.

**PROOF.** \( f_m(x) = (V_{2m}(x))^2 - 3 = V_{2m+1}(x) - 1 = g_{m+1}(x) \), so the conclusion follows from Theorem 11.

Special Issue on Decision Support for Intermodal Transport

Call for Papers

Intermodal transport refers to the movement of goods in a single loading unit which uses successive various modes of transport (road, rail, water) without handling the goods during mode transfers. Intermodal transport has become an important policy issue, mainly because it is considered to be one of the means to lower the congestion caused by single-mode road transport and to be more environmentally friendly than the single-mode road transport. Both considerations have been followed by an increase in attention toward intermodal freight transportation research.

Various intermodal freight transport decision problems are in demand of mathematical models of supporting them. As the intermodal transport system is more complex than a single-mode system, this fact offers interesting and challenging opportunities to modelers in applied mathematics. This special issue aims to fill in some gaps in the research agenda of decision-making in intermodal transport.

The mathematical models may be of the optimization type or of the evaluation type to gain an insight in intermodal operations. The mathematical models aim to support decisions on the strategic, tactical, and operational levels. The decision-makers belong to the various players in the intermodal transport world, namely, drayage operators, terminal operators, network operators, or intermodal operators.

Topics of relevance to this type of decision-making both in time horizon as in terms of operators are:

- Intermodal terminal design
- Infrastructure network configuration
- Location of terminals
- Cooperation between drayage companies
- Allocation of shippers/receivers to a terminal
- Pricing strategies
- Capacity levels of equipment and labour
- Operational routines and lay-out structure
- Redistribution of load units, railcars, barges, and so forth
- Scheduling of trips or jobs
- Allocation of capacity to jobs
- Loading orders
- Selection of routing and service

Before submission authors should carefully read over the journal’s Author Guidelines, which are located at http://www.hindawi.com/journals/jamds/guidelines.html.
