(Received November 28, 1988 and in revised form July 30, 1991)

ABSTRACT. The lower semi-continuity of best approximation operators from Banach lattices onto closed ideals is investigated. Also the existence of best approximation to sub-function modules of function modules is proved. The order intersection properties of cells are studied and used to prove the above results.

KEY WORDS AND PHRASES. Lower semi-continuity, metric projections, continuous selections, finite order intersection properties for cells, Banach lattices, function modules.

1980 Mathematics Subject Classification Codes. 41A30, 41A28.

1. INTRODUCTION AND DEFINITIONS.

During the last 20 years a series of papers have been concerned with continuity of the set valued metric projection from normed linear space onto proximinal linear subspace. Throughout this paper we deal with approximation of elements of the Banach lattice $E$ by elements of a closed ideal $G$. For $x \in E$ we shall denote by $d(x, G) = \inf_{g \in G} \|x - g\|$ the distance from $x$ to $G$. Every $g_o \in G$ for which $\|x - g_o\| = d(x, G)$ is called a best approximation of $x$ in $G$. We shall denote by

$$P_G(x) = \left\{ g \in G : \|x - g\| = d(x, G) \right\} \quad (1.1)$$

the set of all best approximation of $x$ by elements of $G$. The set valued mapping $P : E \rightarrow 2^G$, which associates with each element $x$ of $E$ its (possibly empty) set of nearest elements in $G$, is called the metric projection of $E$ onto $G$ (or the metric projection of $E$ associated with $G$).

In recent years, there has been considerable interest in continuous mapping $s : E \rightarrow G$ with the property that $s(x) \in P_G(x)$ for every $x \in E$. Such a mapping, if exist, is called a continuous selection for the metric projection $P_G$. The available results on continuous selections for the metric projection $P_G$ deal primarily with there existence, which follows directly from the lower semi-continuity of $P_G$ according to a result of E. Michael [8].

For set valued mappings, various concepts of continuity are defined as follows.
DEFINITION 1.1.

(I) The metric projection \( P \) is lower semi-continuous (l.s.c.) if the set
\[
\left\{ x \in E : P_G(x) \cap U \neq \emptyset \right\}
\]
is open for each open set \( U \) in \( G \).

(II) The metric projection \( P_G \) is upper semi-continuous (u.s.c.) if the set
\[
\left\{ x \in E : P_G(x) \cap C \neq \emptyset \right\}
\]
is closed for each closed set \( C \) in \( G \).

(III) Finally, \( P_G \) is continuous (in the Hausdorff metric topology) if
\[
\lim x \implies \max \left\{ \sup \left\{ d(g, P_G(x)) : x \in P_G(x) \right\} , \sup \left\{ d(h, P_G(x)) : h \in P_G(x) \right\} \right\} \to 0.
\]

Continuity in Hausdorff metric topology can be easily shown to imply (l.s.c.). If \( P_G(x) \) is compact for each \( x \) in \( E \) then the Hausdorff metric topology implies (u.s.c.). Finally, if \( G \) is boundedly compact (\( G \) intersects every closed sphere in a compact set) then \( P_G \) is always (u.s.c.) and Hausdorff metric topology is equivalent to (l.s.c.).

The metric projection is (l.s.c.) or (u.s.c.) only for restricted class of subspaces. For example, I. Singer [12] has proved that the metric projection associated with an approximatively compact subset \( G \) of a normed linear space \( E \) is (u.s.c.). Hence, in particular \( P_G \) is (u.s.c.) if \( G \) is a linear subspace of finite dimension. But even if \( G \) is a linear subspace of finite dimension \( P_G \) may fail to be (l.s.c.) as A. J. Lazar, P. P. Morris and D. E. Wulbert have shown in [7].

A subspace \( G \) is proximinal if \( P_G(x) \neq \emptyset \) for each \( x \in E \).

DEFINITION 1.2. A normed linear lattice is a normed linear space which is also a vector lattice, in which the order and the norm are related as follows : \(|x| \leq |y| \) implies \( \|x\| \leq \|y\| \). If the space is complete, it is called Banach lattice.

DEFINITION 1.3. A Banach lattice \( E \) has the order intersection property if whenever elements \( x, y \) and two collections \( \left\{ B(x_s, r_s) \right\}_{s \in A}, \left\{ B(y_b, s_b) \right\}_{b \in B} \) of cells are given in \( E \) satisfying

1. \( x_s \leq x \leq y \leq y_b \) for each \( s, b \)
2. \( B(x_s, r_s) \cap B(y_b, s_b) \neq \emptyset \) for each \( s, b \)
3. \( x \in \bigcap_s B(x_s, r_s) \) and \( y \in \bigcap_b B(y_b, s_b) \)

then
\[
[x, y] \cap \left[ \bigcap_s B(x_s, r_s) \right] \cap \left[ \bigcap_b B(y_b, s_b) \right] \neq \emptyset.
\]

A Banach lattice \( E \) has the f.o.i.p. (finite order intersection property) if the above property holds when the index sets \( A \) and \( B \) are finite. Also : It is known that f.o.i.p., the splitting property and f.o.i.p. in the case \(|A| = |B| = 1\) are equivalent.

We now list some examples of Banach lattices with the f.o.i.p.

1. If \( E \) is an (AL)-space, then it has the f.o.i.p.
2. Every injective Banach lattice (and any closed ideal of it) has the f.o.i.p.
(3) The space $C(x)$ has the f.o.i.p. if and only if $X$ is Stonian.

(4) Any (AM)-space has the f.o.i.p.

For the proofs and general treatment of injective Banach lattices and Banach lattices that have the f.o.i.p., we refer the reader to D. Cartwright [3].

The following fundamental properties of meet, join and the absolute value will be used freely in the sequel:

(1) $x + y = x \vee y + x \land y$.

(2) $|x + y| \leq |x| + |y|$.

(3) $|x - (x \land y)| \leq |(x \vee y) - y|$.

(4) $|x| \land |y| = 0$ if and only if $|x| \vee |y| = |x| + |y|$.

(5) $x \land (y + z) \leq (x \land y) + (x \land z)$ for all $x, y, z \geq 0$.

(6) $|x - y| = x \vee y - x \land y$.

We will prove the following results:

Let $E$ be a Banach lattice with the finite order intersection property, $G$ a closed ideal of $E$. For each $x$ in $E$ define

$P_G^0(x) = \left\{ g \in P_G(x) : x \leq g \leq x^\vee, \text{ and } g \in P_G(x) \right\}$. (1.2)

Then the set valued mapping $P_G^0$ is lower semi-continuous.

Let $E_0$ be a function module and $E$, a sub-$\mathbb{C}(T)$-module of $E_0$. If for each $t$ in $T$, $E_t$ is a Banach lattice with the f.o.i.p. and the fiber $G$ is an ideal in $E_t$, then $E_0$ is proximinal.

**MOTIVATION.** It has been shown in [11] that closed ideals in injective Banach lattices are always proximinal and the metric projections associated with ideals are always (l.s.c.). These results and the fact that injective Banach lattices have the splitting property lead us to think about the above results do hold not only in injective Banach lattices but also in Banach lattices that have the f.o.i.p. The existence of best approximation to ideals in such spaces has been proved (see F. A. Sejeeni [11]).

2. **METRIC PROJECTIONS.**

In order to prove the results stated in the introduction, we need the following partial results which perhaps are interesting in themselves.

**PROPOSITION 2.1.** Let $E$ be a Banach lattice, $G$ a proximinal ideal in $E$.

Then for each positive element $x$ of $E$, the following hold;

(1) $d(x, G) = d(x \vee g, G)$ for each positive $g$ in $G$.

(2) $x \land g \in P_G(x)$ and $g \in P_G(x \vee g)$ for each positive $g \in P_G(x)$.

(3) $(f \vee g) \land x \in P_G(x)$ for all $f, g \geq 0$ such that $f \in G$ and $g \in P_G(x)$.

**PROOF.** (1) Let $g_0$ respectively $(h_0)$ be an arbitrary but fixed element of $P_G(x) \setminus P_G(x \vee g)$. Write $x = x \vee g + x \land g - g$. Then

$d(x, G) = \|x - g_0\| = \|x \vee g + (x \land g - g - g_0)\| \geq d(x \vee g, G)$

(since $- (x \vee g - g - g_0) \in G$). Similarly,

$d(x \vee g, G) = \|x \vee g - h_0\| = \|x - [(x \land g) - g + h_0]\| \geq \|x - g_0\| = d(x, G)$

(since $[(x \land g) - g + h_0] \in G$) and the result follows from (2.1) and (2.2) together.
(2) $|x - (x \land g)| = x - (x \land g) \leq x \lor g - x \land g = |x - g|$ and then
$\|x - (x \land g)\| \leq \|x - g\|$ which in turn implies that $x \land g \in P_G(x)$
(since $x \land g \in G$). Similarly,
$|(x \lor g) - g| = |x - (x \lor g)|$ implies $\|(x \lor g) - g\| = \|x - (x \lor g)\|
= \|x - g\| = d(x, v, g, G)$.

(3) $|x - (f \lor g) \land x| \leq |x - g \land x|$ (since $g \land x \leq (f \lor g) \land x \leq x$) implies
$\|x - (f \lor g) \land x\| \leq \|x - g \land x\| = d(x, g, G)$, hence $\|x - (f \lor g) \land x\|$ implies $d(x, g, G).

PROPOSITION 2.2. Let $E$ be a Banach lattice, $G$ a closed ideal in $E$ and $\alpha$ an element of $G$. If $\beta$ is an element of $G$ and $\epsilon$ is a positive real number such that $\|\alpha - \beta\| \leq r + \epsilon$ (where $r = d(\alpha, G)$), then there is an element $\gamma$ in $G$ such that $\gamma^* \leq \alpha^*$, $\gamma^- \leq \alpha^-$ and $\|\alpha - \gamma\| \leq r + \epsilon$.

PROOF. Define $\gamma^* = \alpha^* \land |\beta|$, $\gamma^* - \alpha^- \land |\beta|$ and $\gamma = \gamma^* - \gamma^-$. Then,
$|\alpha - \gamma| = (\alpha^* - \gamma^*) + (\alpha^- - \gamma^-)$ (since $(\alpha^* - \gamma^*) \land (\alpha^- - \gamma^-) = 0$)
$= |\alpha| - (\alpha^* \land |\beta| + \alpha^- \land |\beta|)$
$\leq |\alpha| - (\alpha^* + \alpha^-) \land |\beta| = |\alpha| - |\alpha| \land |\beta|$,
$\leq |\alpha| \lor |\beta| - |\alpha| \land |\beta| = |\alpha| - |\beta| \leq |\alpha| - |\beta| - |\alpha| - |\beta| = |\alpha| - |\beta|$. Thus, we get $\|\alpha - \gamma\| \leq \|\alpha - \beta\| \leq r + \epsilon$.

PROPOSITION 2.3. Let $E$ be a Banach lattice with the f.o.i.p., $G$ a closed ideal of $E$ and $\alpha$ an element of $G$. If $\beta$ is an element of $G$ such that $\beta^* \leq \alpha^*$, $\beta^- \leq \alpha^-$ and $\|\alpha - \beta\| \leq r + \epsilon$, then there is an element $\gamma$ in $G$ such that $\gamma^* \leq \alpha^*$, $\gamma^- \leq \alpha^-$, $\|\alpha - \gamma\| \leq r + \epsilon$ and $\|\gamma - \beta\| < \epsilon$.

PROOF. Let $\theta$ be a positive best approximation of $|\alpha|$ such that $\theta \leq |\alpha|$
(for the existence of $\theta$ see F. A. Sejeeni [11]). Now,
(1) $|\beta| \leq |\beta| \lor \theta \leq |\alpha|$
(2) $B(|\beta|, \epsilon) \cap B(|\alpha|, r) \neq \emptyset$ (since $|\alpha| - |\beta| \leq r + \epsilon$)
(3) $|\beta| \in B(|\beta|, \epsilon)$ and $|\beta| \lor \theta \in B(|\alpha|, r)$.

Then there exist $\sigma$ in $[\|\beta\|, |\beta| \lor \theta \lor \theta] \cap B(|\beta|, \epsilon) \cap B(|\alpha|, r)$. Define
$\gamma^* = \gamma^* \land |\beta| \land |\beta| \land |\beta|$ and $\gamma^- = \gamma^- \land |\beta| \land |\beta| \land |\beta|$ and note that,
$\sigma = \sigma \land |\alpha| = \sigma \land (\alpha^* \land \alpha^-) \leq \sigma \land \alpha^* + \sigma \land \alpha^- = \gamma^* + \gamma^- = \gamma^* + \gamma^-$. Also:
$\gamma^* \lor \gamma^- = (\sigma \land \alpha^*) \lor (\sigma \land \alpha^-) \leq (\sigma \land |\alpha|) \lor (\sigma \land |\alpha|) = \sigma \lor \sigma = \sigma$. Hence, we
have that $\sigma = \gamma^* + \gamma^-$. We will show that $\gamma = \gamma^* + \gamma^-$ is the desired element of $G$. To see this, note that,
$|\alpha - \gamma| = (\alpha^* - \gamma^*) + (\alpha^- - \gamma^-) = |\alpha| - |\gamma| = |\alpha| - |\gamma| \leq |\alpha| - |\gamma| \leq r$. For the second inequality, note that
$\beta^* \leq \alpha^* \land |\beta|$, $\beta^- \leq \alpha^- \land |\beta|$ and $|\beta| \leq \sigma$ implies that $\beta^* \leq \gamma^*$ and $\beta^- \leq \gamma^-.$
$|\gamma - \beta| = (\gamma^* - \beta^*) + (\gamma^- - \beta^-) = |\gamma| - |\beta| = |\gamma| - |\beta| \leq |\gamma| - |\beta| \leq \|\gamma - \beta\| \leq \|\gamma - \beta\| < \epsilon$.

PROPOSITION 2.4. Let $E$ be a Banach lattice with the f.o.i.p. and $G$ a closed ideal in $E$. Then for each $x$ in $E$, the set $P_G^0(x)$ is a nonempty closed subset of $G$. 

\[\text{PROPOSITION 2.4. Let } E \text{ be a Banach lattice with the f.o.i.p. and } G \text{ a closed ideal in } E. \text{ Then for each } x \text{ in } E, \text{ the set } P_G^0(x) \text{ is a nonempty closed subset of } G.\]
PROOF. Let \( g_1 \) respectively \((g_2, g_3)\) in \( P_G(X) \) \((P_G(x^+))\) be such that \( 0 \leq g_1 \leq x^+ \) \((0 \leq g_2 \leq x^-)\). Let \( h \) in \( P_G(|x|) \) be such that \( g_1 + g_2 \leq h \leq |x| \). Put \( g^+ = x^+ \wedge h \) and \( g = g^+ - g^- \) \((g^+ \in P_G(x^+) \text{ and } |g| \in P_G(|x|))\). Now, let \( f \) be an arbitrary element of \( G \). Then we have \( \| x - f \| \geq \| |x| - |f| \| \geq \| |x| - |g| \| = \| x - g \| \) (since \( |x - g| = \| |x| - |g| \| \)) hence \( g \in P_G^0(x) \). To see it is closed we may assume without loss of generality that \( P_G^0(x) \) is infinite. Let \( \{g_n\}_{n=1}^{+} \) be a sequence in \( P_G^0(x) \) converging to \( g \), then \( g^+ = \lim g_n \) and \( g^- = \lim g_n \) (since \( x = 0 \in G) \). Thus, we have \( g^+ \leq x^+ \text{ and } g^- \leq x^- \). Now, assume that \( P \) is not (l.s.c.) then for some open set \( U \) in \( G \) the set \( \{ y \in P(y) \cup U \neq \emptyset \} \) is not open. Let \( x \in U \) be such that, each neighborhood \( V \) of \( x \) intersects \( U \) in a nonempty set \( U^c \) is the complement of \( U \). The sequence \( \{x_n\} \) converges to \( x \), but it is impossible for any sequence \( \{g_n\} \) with \( g_n \in P(x_n) \) to converge to \( g \) (since \( U \) is a neighborhood of \( g \) and \( g_n \notin G \)).

REMARK. In the following example we will show that it is not always true that if \( g \in P_G(x) \), then \( g^+ \in P_G^0(x) \).

EXAMPLE. Consider the Banach lattice \( E = C([0, \pi]) \), and the ideal \( G = \{ g \in E : g|\pi/2, \pi) = 0 \} \). Let \( x \in E \) be defined by \( x(t) = \max \{- (\sin(t))\} \) = \( (\sin(t))^\ast \). Then the element \( g \in G \), defined by \( g(t) = - \max \{ (\sin(t))\} = - (\sin(t))^\ast \) belongs to \( P_G(x) \) and yet \( g - g \neq 0 \).

PROPOSITION 2.5. The set valued mapping \( P : E \longrightarrow 2^G \) is (l.s.c.) if and only if \( \) for each sequence \( \{x_n\} \) in \( E \) converging to \( x \) and for each \( g \in P(x) \), there is a sequence \( \{g_n\} \) in \( G \) with \( g_n \in P(x_n) \) and \( g_n \) converges to \( g \).

PROOF. Assume that \( P \) is (l.s.c.) \( \{x_n\} \) a sequence in \( E \) converging to \( x \) and \( g \in P(x) \). The set \( U_k = B(g, 2^{-k}) \cap G \) is open in \( G \) \((k \in \mathbb{N})\). Then by (l.s.c.) of \( P \) the set \( U_k = \{ y \in P(y) \cap U_k \neq \emptyset \} \) is a neighborhood of \( x \). Hence, there exists an integer \( N_k \in \mathbb{N} \) such that \( x_n \in U_k \), and then, \( P(x_n) \cap U_k \neq \emptyset \) for each \( n \geq N_k \). Now, we can select a sequence \( \{g_n\} \) such that \( g_n \in P(x_n) \) and \( \| g_n - g \| \leq 2^{-k} \) \((n \geq N_k)\).

THEOREM 2.6. Let \( E \) be a Banach lattice with the f.o.i.p, and \( G \) a closed ideal in \( E \). Then the set valued mapping \( P^0_G : E \longrightarrow 2^G \) defined by \( P^0_G(x) = \{ g \in P_G(x) : g^\ast \leq x^+ \text{ and } g \in P_G(x^+) \} \) is always (l.s.c.).

PROOF. First, we will show that the result holds for positive elements. Let \( \{x_n\} \) be a positive sequence in \( E \) converging to \( x \) \((x \geq 0)\), and \( g \in P^0_G(x) \). For each \( n \in \mathbb{N} \), let \( h_n \in P^0_G(x_n) \). If \( \varepsilon \) is a positive real number then, we have

1. \( g \wedge x_n \leq g \wedge x_n \leq (g \vee h_n) \wedge x_n \leq x_n \)
2. \( B(g \wedge x_n, \varepsilon) \cap B(x_n, x_n) \neq \emptyset \)
\[ \left\{ \text{since } \|x_n - g \wedge x_n\| \leq \|x_n - x\| + \|x - g\| + \|g - g \wedge x_n\| \leq \epsilon/3 + r + \epsilon/3 < \epsilon/3 + (r_n + \epsilon/3) + \epsilon/3 = r_n + \epsilon \right\} \forall n \geq N_\epsilon \text{ where } r_n = d(x_n, G) \text{ and } r = d(x, G) \]

(3) \( g \wedge x_n \in B(g \wedge x_n, \epsilon) \) and \( (g \vee h_n) \wedge x_n \in B(x_n, r_n) \).

Then for each \( n \geq N_\epsilon \) there is a \( g_n \) in 
\[ [g \wedge x_n, (g \vee h_n) \wedge x_n] \cap B(g \wedge x_n, \epsilon) \cap B(x_n, r_n) \].

Now, for \( n \in \mathbb{N} \) take \( \epsilon = \epsilon_n = 3 \max \left\{ \|x_n - x\|, |r_n - r|, \|g - g \wedge x_n\| \right\} \). Thus we can select a sequence \( \{g_n\} \)

such that \( g_n \in \mathcal{P}_G^0(x_n) \) and \( |g_n - (g \wedge x_n)| \leq \epsilon_n \). The sequence \( \{g_n\} \) is the desired sequence (since \( \|g_n - g\| \leq \|g_n - (g \wedge x_n)\| + \|g \wedge x_n - g\| \rightarrow 0 \)).

Now, let \( \{x_n\} \) be an arbitrary sequence in \( E \) converging to \( x \) and \( g \) an arbitrary element of \( \mathcal{P}_G^0(x) \). Then by the above there are positive sequences \( \{f_n\}, \{h_n\} \) and \( \{k_n\} \) in \( G \) such that \( f_n \in \mathcal{P}_G^0(x_n^+), h_n \in \mathcal{P}_G^0(x_n^-), k_n \in \mathcal{P}_G^0(|x_n|) \), 
\[ f_n \rightarrow g^+, h_n \rightarrow g^- \text{ and } k_n \rightarrow |g| \]. We may assume without loss of generality that \( f_n + h_n \leq k_n \) (otherwise set \( k_n = k_n + (f_n + h_n) \)). Now set \( g_n = g_n^+ = k_n \geq f_n, \)

\[ g_n = g_n^+ - g_n^- \] (it is obvious that \( g_n \rightarrow g \)).

To complete the proof, we will show that \( g_n \in \mathcal{P}_G^0(x_n) \). To see this, let \( y \) be an arbitrary element of \( G \), then \( \|x_n - y\| \geq \|x_n\| - |y| \geq \|x_n\| - k_n \) (the first inequality holds since \( |x_n - y| \geq \|x_n\| - |y| \) while the second one holds because \( k_n \in \mathcal{P}_G^0(|x_n|) \)). But, \( |x_n| \geq |g_n| = g_n^+ + g_n^- = x_n^+ \wedge k_n + x_n^- \wedge k_n \geq \|x_n\| \wedge k_n \), then \( |x_n - y| \geq \|x_n\| - |y| \geq \|x_n\| - |g_n| \geq \|x_n - g_n\| \) which implies that \( \|x_n - g_n\| = d(x_n, G) \) i.e., \( g_n \in \mathcal{P}_G^0(x_n) \).

3. FUNCTION MODULES.

DEFINITION 3.1. Let \( A \) be a Banach algebra with a norm \( \| \cdot \|_A \), and let \( E \) be a Banach space. We say that \( E \) is a Banach \( A \)-module if

(i) \( E \) is a left module over \( A \) in the usual algebraic sense;

(ii) there is a positive constant \( k \) such that \( \|ax\| \leq k \|a\|_A \|x\| \) for all \( a \in A, x \in E \).

Let \( T \) be a nonvoid compact Hausdorff space \( (E_t)_{t \in T} \) a family of Banach spaces. The product \( \prod_{t \in T} E_t \) can be thought of as a space of functions on \( T \) where the values of the functions at different points lie (possibly) in different spaces. We will restrict our attention to the subspace

\[ \prod_{t \in T}^\circ E_t := \left\{ \alpha \in \prod_{t \in T} E_t : \|\alpha\|_\infty = \sup_{t \in T} \|\alpha(t)\|_t < \infty \right\} \]

(where \( \| \cdot \|_t \) is the norm on the Banach space \( E_t \)).

DEFINITION 3.2. A function module is a triple \( \left( T, (E_t)_{t \in T}, E_\infty \right) \), where \( T \) is a nonvoid compact Hausdorff space (called the base space), \( (E_t)_{t \in T} \) a family of Banach spaces (the component spaces) and \( E_\infty \) a closed subspace of \( \prod_{t \in T} E_t \) such that the following are satisfied:
(1) $E_\omega$ is a $C(T)$-module (where $C(T)$ is the Banach algebra of all continuous scalar valued functions on $T$) $(f, \alpha)(t) = f(t)\alpha(t)$, $f \in C(T)$, $\alpha \in E_\omega$.

(2) For every $\alpha \in E_\omega$, the map $t \mapsto \|\alpha(t)\|_t$ is upper semi-continuous.

(3) $E_t = \{ \alpha(t) : \alpha \in E_\omega \}$ for every $t \in T$.

(4) $\{ t : t \in T, E \neq \{0\} \} = T$.

A sub-function module is a subspace which is a $C(T)$-module. A function module of Banach lattices is a function module such that the components $E_t$ are Banach lattices and $E_\omega$ is closed under the the lattice operations $\wedge$ and $\vee$ which are defined pointwise $((\alpha \vee \beta)(t) = \alpha(t) \vee \beta(t))$.

**DEFINITION 3.3.** Let $E_\omega$ be a function module in $\prod_{t \in T} E_t$, $E_\omega$ a sub-function module of $E_\omega$, $E_\omega$ an element of $E_\omega$. Then,

(i) the element $\gamma$ of $E_\omega$ is global best approximation of $\alpha$ if

$$\|\alpha - \gamma\|_\omega = \sup_{t \in T} \|\alpha(t) - \gamma(t)\|_t = \inf \left\{ \|\alpha - \beta\|_\omega : \beta \in E_\omega \right\}.$$ 

(ii) the element $\gamma$ is a local best approximation of $\alpha$ if

$$\|\alpha(t) - \gamma(t)\|_t = \inf \left\{ \|\alpha(t) - g\|_t : g \in G_t \right\} \text{ i.e., } \gamma(t) \in P_{G_t} (\alpha(t)) \text{ } (t \in T).$$

**LEMMA 3.4.** Let $E_\omega$ be a function module of Banach lattices and $E_\omega$ a sub-function module of $E_\omega$ such that the fiber $G_t$ is an ideal in $E_t$. Then for each $\alpha \in E_\omega$ and for each positive real numbers $\varepsilon$ there is an element $\gamma$ in $E_\omega$ such that $\|\alpha - \gamma\|_\omega \leq r + \varepsilon$. $(\alpha(t))^+ \leq (\gamma(t))^+$ and $(\alpha(t))^- \leq (\gamma(t))^-$ for each $t \in T$ (where $r = d(\alpha, G)$).

**PROOF.** Let $\beta \in E_\omega$ be such that $\|\alpha - \beta\|_\omega \leq r + \varepsilon$. For $t \in T$ define $\gamma_1(t) = (\alpha(t))^+ \wedge |\beta(t)|$ and $\gamma_2(t) = (\alpha(t))^- \wedge |\beta(t)|$. Then $\gamma_i \in \prod_{t \in T} G_t = E_\omega$ $i = 1, 2$.

Let $\gamma = \gamma_1 - \gamma_2$, then for each $t \in T$ we have

$$|\alpha(t) - \gamma(t)| = \left|\left((\alpha(t))^+ - (\alpha(t))^-\right) - (\gamma_1(t) - \gamma_2(t))\right|$$

$$= \left|\left((\alpha(t))^+ - \gamma_1(t)\right) - \left((\alpha(t))^- - \gamma_2(t)\right)\right|$$

$$= \left|\left((\alpha(t))^+ - \gamma_1(t)\right) + \left((\alpha(t))^+ - \gamma_2(t)\right)\right|$$

$$= |\alpha(t)| - |\gamma(t)|$$

$$\leq |\alpha(t)| \vee |\beta(t)| - \left|\left((\alpha(t))^+ \wedge |\beta(t)| + (\alpha(t))^+ \wedge |\beta(t)|\right)\right|$$

$$\leq |\alpha(t)| \vee |\beta(t)| - |\alpha(t)| \wedge |\beta(t)|$$

$$= |\alpha(t)| - |\beta(t)| \leq |\alpha(t) - \beta(t)|.$$ 

Hence $\|\alpha(t) - \gamma(t)\|_t = 1 0 \|\alpha(t) - \beta(t)\|_t \leq r + \varepsilon$.

**THEOREM 3.5.** Let $E_\omega$ be a function module of Banach lattices and $E_\omega$ a sub-function module of $E_\omega$. If for each $t \in T$ the space $E_t$ has the f.o.i.p. and the fiber $G_t$ is an ideal of $E_t$, then $E_\omega$ is proximinal.

**PROOF.** Let $\alpha$ be an element of $E_\omega$, $\varepsilon$ a positive real number and $r = d(\alpha, G)$. Then by lemma 3.4 there is a $\gamma$ in $E_\omega$ such that $\|\alpha - \gamma\| \leq r + \varepsilon$ and $(\gamma(t))^\mp \leq (\alpha(t))^\mp$ for each $t \in T$. Now, by proposition 2.3 there is a $g_t$ in $G_t$ such that
\[ \| \alpha(t) - g_t \|_t \leq r \quad \text{and} \quad \| g_t - \gamma(t) \|_t \leq \varepsilon . \quad (3.1) \]

Put \( f_t = 1/2(\gamma(t) + g_t) \), then

\[ \| \alpha(t) - f_t \|_t \leq r + \varepsilon/2 \quad \text{and} \quad \| f_t - \gamma(t) \|_t \leq \varepsilon/2 . \quad (3.2) \]

Let \( \gamma_t \in E_0 \) be such that \( \gamma_t(t) = f_t \) and \( U_t \) a neighborhood of \( t \) such that for each \( s \in U_t \) we have

\[ \| \alpha(s) - \gamma_t(s) \|_s \leq r + \varepsilon/2 \quad \text{and} \quad \| \gamma(s) - \gamma_t(s) \|_s \leq \varepsilon/2 . \quad (3.3) \]

The collection \( \{ U_t \mid t \in T \} \) forms an open covering of \( T \). Let \( t_1, \ldots, t_n \) in \( T \) be such that \( T = \bigcup_{i=1}^{n} t_i \) and \( \{ f_i \}_{i=1}^{n} \) the partition of unity subordinate to \( \{ U_i \}_{i=1}^{n} \). Set \( \gamma_0 = \sum_{i=1}^{n} f_i \cdot \gamma_{t_i} \) then for \( t \in T \)

\[ \| \alpha(t) - \gamma_0(t) \| = \left\| \sum_{i=1}^{n} f_i(t) \cdot \alpha(t) - \sum_{i=1}^{n} f_i(t) \cdot \gamma_{t_i}(t) \right\| \]

\[ \leq \sum_{i=1}^{n} | f_i(t) | \cdot \left\| \alpha(t) - \gamma_{t_i}(t) \right\| \]

\[ \leq r + \varepsilon/2 . \]

Similarly \( \| \gamma - \gamma_0 \| \leq \varepsilon/2 . \)

\[ \| \alpha - \gamma_0 \|_{\infty} \leq r + \varepsilon/2 \quad \text{and} \quad \| \gamma - \gamma_0 \|_{\infty} \leq \varepsilon/2 . \quad (3.4) \]

Taking \( \varepsilon = 2^{-n} \) \((n \in \mathbb{N})\) we can construct a sequence \( \{ \gamma_n \} \) satisfying

\[ \| \alpha - \gamma_n \| \leq r + 2^{-n} \quad \text{and} \quad \| \gamma_n - \gamma_{n+1} \| \leq 2^{-n} . \quad (3.5) \]

The second inequality of (3.5) implies that \( \{ \gamma_n \} \) is Cauchy, and then it has a limit \( \gamma \) in \( E_0 \). The first inequality of (3.5) implies that \( \gamma \in F_0^G G(\alpha) \).

**PROPOSITION 3.6.** Let \( T \) be a compact Hausdorff space, \( E \) a Banach lattice with the f.o.i.p. and \( G \) a closed ideal of \( E \). Then \( C(T,G) \) contains local and global best approximation for each \( f \) in \( C(T,E) \).

**PROOF.** The existence of global best approximation follows from theorem 3.5 and the fact that the space \( C(T,G) \) is an ideal in the Banach lattice \( C(T,E) \).

For local best approximation, we define \( P : T \rightarrow 2^G \) by \( P(t) = P_G^0 (f(t)) \) (where \( P_G^0 (f(t)) \) is the set of all best approximation of \( f(t) \) in \( G \) satisfying (1.2) ). Then set valued mapping \( P \) is (l.s.c.) since \( P = (P_G^0 \circ f) \), \( f \) is continuous and \( P_G^0 \) is (l.s.c.). Let \( s \) be a continuous selection of \( P \), then \( g = s \circ f \) is desired element of \( G \).

Finally, we conclude this paper with the observation that in some cases global best approximation always exists and yet the set valued mapping \( P \) defined above admits no continuous selection at all as we will see in the following.
EXAMPLE. Let $E_\infty = C([0,1],\mathbb{R})$ (the space of all continuous real valued functions on $[0,1]$ with $\|f\| = \sup_{t \in T}|f(t)|$), $E_\infty^0$ the space of all $f$ in $E_\infty$ which vanish on $[0,1/2]$. If we take $f \in E_\infty$ to be the constant function $f(t) = 1$ ($t \in T$). Then we have the following:

$$G_t = \begin{cases} \{0\} & \text{for } t \in [0,1/2] \\ \mathbb{R} & \text{for } t \in (1/2,1] \end{cases} \quad \text{and} \quad P(t) = \begin{cases} \{0\} & \text{if } t \in [0,1/2] \\ \{1\} & \text{if } t \in (1/2,1] \end{cases}.$$ 

Thus $P$ is a single valued discontinuous function on $[0,1]$ which admits no continuous selection at all.

REFERENCES

Special Issue on
Boundary Value Problems on Time Scales

Call for Papers

The study of dynamic equations on a time scale goes back to its founder Stefan Hilger (1988), and is a new area of still fairly theoretical exploration in mathematics. Motivating the subject is the notion that dynamic equations on time scales can build bridges between continuous and discrete mathematics; moreover, it often reveals the reasons for the discrepancies between two theories.

In recent years, the study of dynamic equations has led to several important applications, for example, in the study of insect population models, neural network, heat transfer, and epidemic models. This special issue will contain new research and survey articles on Boundary Value Problems on Time Scales. In particular, it will focus on the following topics:

- Existence, uniqueness, and multiplicity of solutions
- Comparison principles
- Variational methods
- Mathematical models
- Biological and medical applications
- Numerical and simulation applications

Before submission authors should carefully read over the journal's Author Guidelines, which are located at http://www.hindawi.com/journals/ade/guidelines.html. Authors should follow the Advances in Difference Equations manuscript format described at the journal site http://www.hindawi.com/journals/ade/. Articles published in this Special Issue shall be subject to a reduced Article Processing Charge of €200 per article. Prospective authors should submit an electronic copy of their complete manuscript through the journal Manuscript Tracking System at http://mts.hindawi.com/ according to the following timetable:

<table>
